Children are Hair or Emitter particles originating from individual particles. They allow to work with a relatively low amount of Parent particles. Which reduces the calculation effort.

If you activate children, then the parents are no longer rendered. They can be re-enabled in the Render panel in the Extras subpanel. Parent Particles. By default, parent particles are not rendered because the shape of the children can be quite different from that of their parents.

## Children panel - Type None

### Child Type

#### None

No children are generated. No settings.

## Children panel - Type Simple

### Simple

Children are emitted from the parent position.

#### **Display Amount**

The number of children in the 3D Viewport.

#### **Render Amount**

The number of children to be rendered.

#### **Length**

Length of child paths.

#### **Threshold**

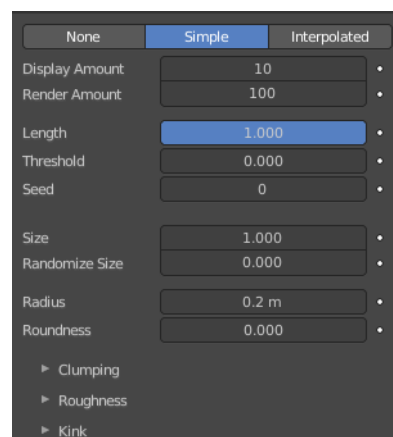

Amount of particles left untouched by child path length.

#### **Seed**

Offset in the random number table for child particles, to get a different randomized result.

#### **Size**

A multiplier for children size.

## Random Size

Random variation to the size of child particles

## Radius

The radius in which the children are distributed around their parents. This is 3D, so children may be emitted higher or lower than their parents.

## Roundness

The roundness of the children around their parents. Either in a sphere (1.0) or in-plane (0.0).

# Children panel - Type Simple - Clumping subpanel

Clumping allows as the name says to break the even look, and clump particles together.

## Use Clump Curve

Use a Curve instead of parameters to adjust the clumping.

## Selecting Points

You can select curve points. This reveals two edit boxes for the x and y coordinate of this point.

Selected points can be moved around. Left click at them, hold the mouse button down and move them to a new location.

## Adding Points

You can add new curve points by simply left clicking at the curve. Move the mouse to position them where you need it.

## Navigation elements

The navigation elements at the top are described from left to right.

### ***Zoom in and out***

The two buttons with the magnifying glass at it zooms in and out in the curve window.

---

## ***Tools***

Tools is a menu where you can find some curve related tools.

### **Reset View**

Resets the curve windows zoom.

### **Vector Handle**

Set handle type to Vector.

### **Auto Handle**

Set handle type to Auto.

### **Extend horizontal**

Extend the curve horizontally before the first and after the last curve point.

### **Extend vertical**

Extend the curve vertically before the first and after the last curve point.

### **Auto Clamped Handle**

Set handle type to Auto Clamped.

### **Reset Curve**

Resets the curve to the initial shape.

---

## ***Use Clipping***

Clipping options. Set up clipping for the stroke.

### ***Delete Points***

Deletes selected curve points.

## **Clump**

Clumping amount along child strands. The children may meet at their tip (1.0) or start together at their root (-1.0).

## Shape

Form of Clump. Either inverse parabolic (0.99) or exponentially (-0.99).

## Twist

Number of turn around parent along the strand.

## Use Twist Curve

Use a Curve instead of parameters to adjust the twisting of the particles.

For controls see above, clump curve.

## Clump Noise

Creates random clumps around the parent hair.

## Clump Noise Size

The size of clump noise.

# Children panel - Type Simple + Interpolated - Roughness sub-panel

Give the particles a roughness.

## Use Roughness Curve

Use Curve Widget instead of parameters.

## Selecting Points

You can select curve points. This reveals two edit boxes for the x and y coordinate of this point.

Selected points can be moved around. Left click at them, hold the mouse button down and move them to a new location.

## Adding Points

You can add new curve points by simply left clicking at the curve. Move the mouse to position them where you need it.

## Navigation elements

The navigation elements at the top are described from left to right.

### *Zoom in and out*

The two buttons with the magnifying glass at it zooms in and out in the curve window.

## Tools

Tools is a menu where you can find some curve related tools.

### Reset View

Resets the curve windows zoom.

### Vector Handle

Set handle type to Vector.

### Auto Handle

Set handle type to Auto.

### Extend horizontal

Extend the curve horizontally before the first and after the last curve point.

### Extend vertical

Extend the curve vertically before the first and after the last curve point.

### Auto Clamped Handle

Set handle type to Auto Clamped.

## Reset Curve

Resets the curve to the initial shape.

## Use Clipping

Clipping options. Set up clipping for the stroke.

## Delete Points

Deletes selected curve points.

## Roughness

Amount of location dependent roughness.

## Size

Size of location dependent roughness.

## Uniform, Size

It is based on children location so it varies the paths in a similar way when the children are near.

## Endpoint, Shape

“Rough End” randomizes path ends (a bit like random negative clumping). Shape may be varied from <1 (parabolic) to 10.0 (hyperbolic).

## Random, Size, Threshold

It is based on a random vector so it is not the same for nearby children. The threshold can be specified to apply this to only a part of children. This is useful for creating a few stray children that will not do what others do.

# Children panel - Type Simple + Interpolated - Kink subpanel

With Kink you can rotate the children around the parent.

## Kink Type

## Nothing

Deactivated.

## Curl, Radial, Wave, Braid

Curl - Children grow in a spiral around the parent hairs.

Radial - Children form around the parent a wave shape that passes through the parent hair.

Wave - Children form a wave, all in the same direction.

Braid - Children braid themselves around the parent hair.

### **Amplitude**

The amplitude of the offset.

### **Clump**

How much clump effects kink amplitude.

### **Flatness**

How flat the hairs are.

### **Frequency**

The frequency of the offset (1/total length). The higher the frequency the more rotations are done.

### **Shape**

Where the rotation starts (offset of rotation).

## Spiral

Generates a spiral at the end of each hair.

### **Amplitude**

The amplitude of the offset.

### **Randomize Amplitude**

Give the amplitude a random variation.

### **Axis**

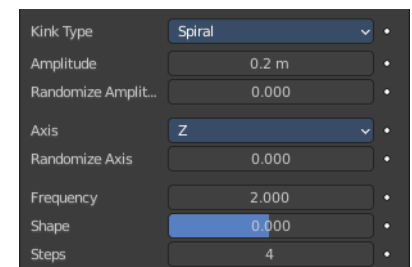

Which axis to use for offset.

### **Randomize Axis**

Randomize the orientation.

### **Frequency**

The frequency of the offset (1/total length). The higher the frequency the more rotations are done.

## Shape

Where the rotation starts (offset of rotation).

## Steps

Extra steps for resolution of special kink features.

# Children panel - Type Interpolated

Children are emitted between the Parent particles on the faces of a mesh. They interpolate between adjacent parents. This is especially useful for fur, because you can achieve an even distribution. Some of the children can become virtual parents, which are influencing other particles nearby.

## Display Amount

The number of children in the 3D Viewport.

## Render Amount

The number of children to be rendered.

## Length

Length of child paths.

## Threshold

Amount of particles left untouched by child path length.

## Seed

Offset in the random number table for child particles, to get a different randomized result.

## Virtual Parents

Relative Amount of virtual parents.

## Long Hair

Belongs to Hair particles. Calculate children that suit long hair well.

## Children panel - Type Interpolated - Parting subpanel

This panel belongs to Hair particles.

### Parting

Creates parting in the children based on parent strands.

### Min

Minimum root to tip angle. Tip distance / root distance for long hair.

### Max

Maximum root to tip angle. Tip distance / root distance for long hair.

## Children panel - Type Interpolated - Clumping subpanel

Clumping allows as the name says to break the even look, and clump particles together.

### Use Clump Curve

Use a Curve instead of parameters to adjust the clumping.

### Selecting Points

You can select curve points. This reveals two edit boxes for the x and y coordinate of this point.

Selected points can be moved around. Left click at them, hold the mouse button down and move them to a new location.

### Adding Points

You can add new curve points by simply left clicking at the curve. Move the mouse to position them where you need it.

## Navigation elements

The navigation elements at the top are described from left to right.

### ***Zoom in and out***

The two buttons with the magnifying glass at it zooms in and out in the curve window.

---

## ***Tools***

Tools is a menu where you can find some curve related tools.

### **Reset View**

Resets the curve windows zoom.

### **Vector Handle**

Set handle type to Vector.

### **Auto Handle**

Set handle type to Auto.

### **Extend horizontal**

Extend the curve horizontally before the first and after the last curve point.

### **Extend vertical**

Extend the curve vertically before the first and after the last curve point.

### **Auto Clamped Handle**

Set handle type to Auto Clamped.

### **Reset Curve**

Resets the curve to the initial shape.

---

## ***Use Clipping***

Clipping options. Set up clipping for the stroke.

### ***Delete Points***

Deletes selected curve points.

## **Clump**

Clumping amount along child strands. The children may meet at their tip (1.0) or start together at their root (-1.0).

## Shape

Form of Clump. Either inverse parabolic (0.99) or exponentially (-0.99).

## Clump Noise

Creates random clumps around the parent hair.

## Clump Noise Size

The size of clump noise.

## 26.10.1 Editors - Properties Editor - Particle Properties Tab - Emitter

### Table of content

Introduction.....	1
Workflow example.....	1

## Introduction

There are two types of particles. Emitted particles and hair. Emitted particles are used for things like fire, smoke, mist and many other animated effects. Hair is used for hair and fur effects, at characters for example.

This manual part is for particles of type Emitter.

### Workflow example

Create a plane.

Add a particle system.

Hit play. You will now see particles falling down from the plane.

Now you can start to tweak the settings until you are satisfied.

## Force Field Settings panel

The Force Field Settings panel allows you to make each individual act as a force field, allowing them to affect other dynamic systems, or even, each other.

### Self Effect

Causes the particle force fields to have an effect on other particles within the same system.

### Effector Amount

Set how many of the particles act as force fields. 0 means all of them are effectors.

### Type 1 and Type 2 Sub panels

You can give particle systems up to two force fields. By default they do not have any force field enabled. Choose an effector type from the selector to enable them.

### Type 1 / 2

#### **Force**

Radial field towards the center of an object.

#### **Strength**

The strength of the force.

#### **Flow**

Convert effector force into air force velocity.

#### **Affect**

##### **Location**

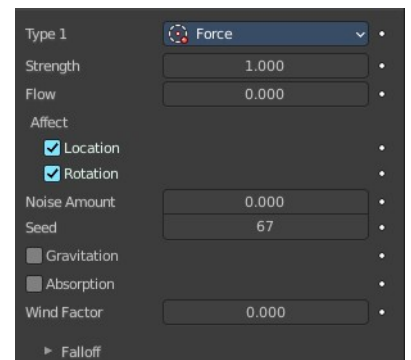

Affect the location of the particles.

##### **Rotation**

Affect the rotation of the particles.

##### **Noise Amount**

Amount of noise for the force effect.

## Seed

The random seed for the noise amount.

## Gravitation

Multiply force by 1 divided through the distance in square.

## Absorption

Force gets absorbed by collision objects.

## Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

---

## Wind

Constant force along the Z axis.

### Strength

The strength of the force.

### Flow

Convert effector force into air force velocity.

### Affect

#### Location

Affect the location of the particles.

#### Rotation

Affect the rotation of the particles.

### Noise Amount

Amount of noise for the force effect.

### Seed

The random seed for the noise amount.

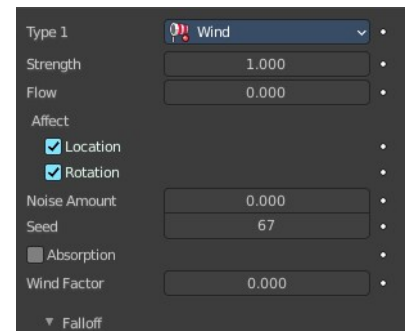

### Absorption

Force gets absorbed by collision objects.

### Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

---

## ***Vortex***

Spiraling force that twists the force object's local Z axis.

### **Strength**

The strength of the force.

### **Flow**

Convert effector force into air force velocity.

### **Affect**

#### ***Location***

Affect the location of the particles.

#### ***Rotation***

Affect the rotation of the particles.

### **Noise Amount**

Amount of noise for the force effect.

### **Seed**

The random seed for the noise amount.

### **Absorption**

Force gets absorbed by collision objects.

### **Wind Factor**

How much the force is reduced when acting parallel to a surface. Like a cloth.

## ***Magnetic***

Force field depends of the speed of the particles.

### **Strength**

The strength of the force.

### **Flow**

Convert effector force into air force velocity.

### **Affect**

#### ***Location***

Affect the location of the particles.

#### ***Rotation***

Affect the rotation of the particles.

## Noise Amount

Amount of noise for the force effect.

## Seed

The random seed for the noise amount.

## Absorption

Force gets absorbed by collision objects.

## Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

---

## Harmonic

The source of this force field is the zero point of a harmonic oscillator.

### Strength

The strength of the force.

### Damping

Damping of the harmonic force.

### Rest Length

The rest length of the harmonic force.

### Affect

#### Location

Affect the location of the particles.

#### Rotation

Affect the rotation of the particles.

### Noise Amount

Amount of noise for the force effect.

### Seed

The random seed for the noise amount.

### Multiple Springs

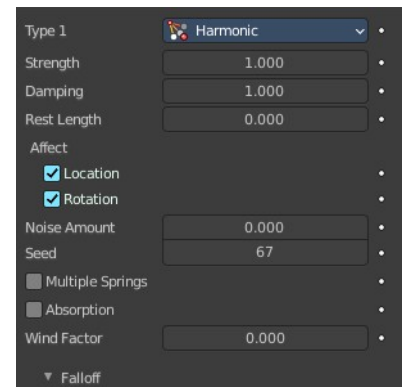

Every point is effected by multiple springs.

### Absorption

Force gets absorbed by collision objects.

### Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

## **Charge**

Special force field based on the charge of particles. Charge force fields just affects other charge force fields.

## **Strength**

The strength of the force.

## **Flow**

Convert effector force into air force velocity.

## **Affect**

### **Location**

Affect the location of the particles.

### **Rotation**

Affect the rotation of the particles.

## **Noise Amount**

Amount of noise for the force effect.

## **Seed**

The random seed for the noise amount.

## **Absorption**

Force gets absorbed by collision objects.

## **Wind Factor**

How much the force is reduced when acting parallel to a surface. Like a cloth.

---

## **Lenard Jones**

Force field based on the lennard jones potential. The Lennard-Jones potential describes the interactions of two neutral particles using a relatively simple mathematical model.

## **Strength**

The strength of the force.

## **Flow**

Convert effector force into air force velocity.

## **Affect**

### ***Location***

Affect the location of the particles.

### ***Rotation***

Affect the rotation of the particles.

## **Noise Amount**

Amount of noise for the force effect.

## **Seed**

The random seed for the noise amount.

## **Absorption**

Force gets absorbed by collision objects.

## **Wind Factor**

How much the force is reduced when acting parallel to a surface. Like a cloth.

---

## ***Texture***

Force field based on a texture. There is no way to add a texture here though.

## **Strength**

The strength of the force.

## **Flow**

Convert effector force into air force velocity.

## **Affect**

### ***Location***

Affect the location of the particles.

### ***Rotation***

Affect the rotation of the particles.

## **Noise Amount**

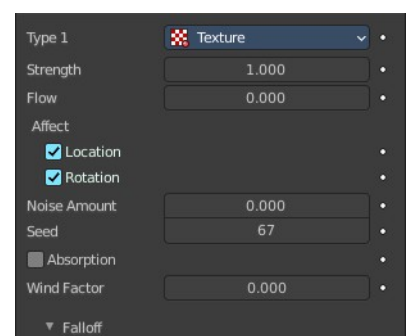

Amount of noise for the force effect.

## **Seed**

The random seed for the noise amount.

## **Absorption**

Force gets absorbed by collision objects.

## Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

---

## Curve Guide

Creates a force along a curve object. There is no way to add a curve here though.

## Strength

The strength of the force.

## Flow

Convert effector force into air force velocity.

## Affect

### Location

Affect the location of the particles.

### Rotation

Affect the rotation of the particles.

## Noise Amount

Amount of noise for the force effect.

## Seed

The random seed for the noise amount.

## Absorption

Force gets absorbed by collision objects.

## Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

---

## Boid

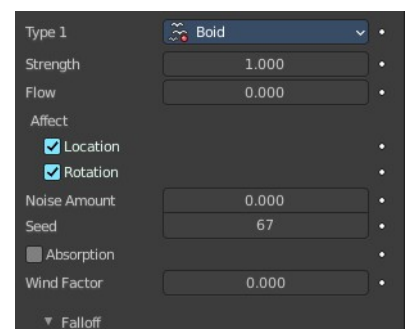

Creates a force that acts as a boid's predator or target.

## Strength

The strength of the force.

## Flow

Convert effector force into air force velocity.

## **Affect**

### ***Location***

Affect the location of the particles.

### ***Rotation***

Affect the rotation of the particles.

## **Noise Amount**

Amount of noise for the force effect.

## **Seed**

The random seed for the noise amount.

## **Absorption**

Force gets absorbed by collision objects.

## **Wind Factor**

How much the force is reduced when acting parallel to a surface. Like a cloth.

---

## ***Turbulence***

Create turbulence with a noise field.

## **Strength**

The strength of the force.

## **Size**

The size of the turbulence.

## **Flow**

Convert effector force into air force velocity.

## **Affect**

### ***Location***

Affect the location of the particles.

### ***Rotation***

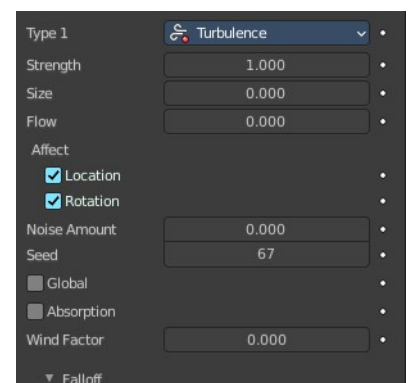

Affect the rotation of the particles.

## **Noise Amount**

Amount of noise for the force effect.

## **Seed**

The random seed for the noise amount.

## Global

Use global coordinates for the turbulence.

## Absorption

Force gets absorbed by collision objects.

## Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

---

## Drag

Create a force that dampens motion.

## Linear

Drag component proportional to velocity.

## Quadratic

Drag component proportional to square velocity.

## Affect

### Location

Affect the location of the particles.

### Rotation

Affect the rotation of the particles.

## Noise Amount

Amount of noise for the force effect.

## Seed

The random seed for the noise amount.

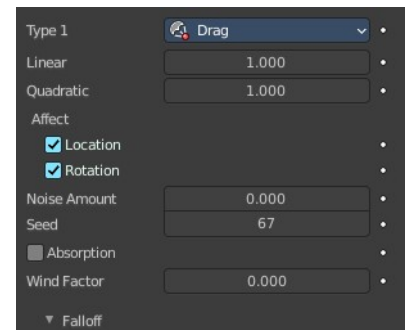

## Absorption

Force gets absorbed by collision objects.

## Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

---

## ***Fluid Flow***

Create a force field based on fluid simulation velocities.

### **Strength**

The strength of the force.

### **Flow**

Convert effector force into air force velocity.

### **Affect**

#### ***Location***

Affect the location of the particles.

#### ***Rotation***

Affect the rotation of the particles.

### **Noise Amount**

Amount of noise for the force effect.

### **Seed**

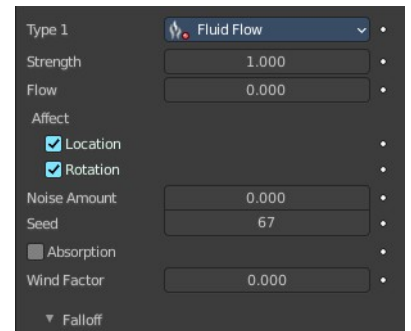

The random seed for the noise amount.

### **Absorption**

Force gets absorbed by collision objects.

### **Wind Factor**

How much the force is reduced when acting parallel to a surface. Like a cloth.

## **Falloff subpanel**

### ***Z Direction***

Apply the effect in both directions along Z axis, or just one direction.

### **Power**

How quickly the strength falls off with increasing distance from the force field.

### ***Min Distance***

Minimum distance for the fields falloff.

### ***Max Distance***

Maximum distance for the fields falloff.

## 26.10.21 Editors - Properties Editor - Particle Properties Tab - Vertex Groups panel

### Table of content

Vertex Groups panel.....	1
Density.....	1
Length.....	1
Clump.....	1
Kink.....	1
Roughness 1.....	1
Roughness 2.....	1
Roughness End.....	2
Twist.....	2

### Vertex Groups panel

The Vertex groups panel allows you to specify vertex groups to use for several child particle settings. You can also negate the effect of each vertex group with the check boxes. You can affect the following attributes:

#### Density

Defines the density of the particle distribution.

#### Length

Defines the length of the hair.

#### Clump

Controls the amount of clumping. The weight of 1.0 gives current Clump value, weight of 0.0 completely removes effect.

#### Kink

Controls the frequency of the children Kink.

#### Roughness 1

Adjusts the Uniform roughness parameter.

#### Roughness 2

Adjusts the Random roughness parameter.

## **Roughness End**

Adjusts the Endpoint roughness parameter.

## **Twist**

Vertex group to control the children's Twist effect. Gives control over the direction of the twist, as well as the amount. The weight of 0.5 is neutral, i.e. there is no twist effect.

## 26.10.22 Editors - Properties Editor - Particle Properties Tab - Textures panel

### Table of content

Remove.....	2
Change Context.....	2

## Textures panel

Particles density can be controlled by textures. This panel allows you to set up the required textures. There can just be one active texture.

### Texture Slot List

The list with the texture slots. You can rename the slots by double clicking at it.

These slots are empty when you create them. You need to fill the slots with textures. This can be done in the Textures tab.

### Move Texture Slot Up / Down

Move the texture slots up or down in the list.

### Texture Specials

#### Copy Texture Slot Settings

Copies the Texture Slot Settings.

#### Paste Texture Slot Settings

Pastes copied Texture Slot Settings.

## Image slot property

### Texture Browser

A list of the textures in the scene. This list allows you to switch to other textures.

### New

When nothing is loaded then you will see the New button to create a new image slot.

### Texture Edit Box

The name of the currently selected texture. A double left click allows you to rename it.

### Fake User

With this button you assign a fake user to this selected image.

Data, like images, that is not longer linked to anything else gets removed when you save and reload a scene. Bforartists has the concept of fake users to go around this behavior. An image with a fake user is in fact linked to something. And so it is not lost when you save and reload the scene.

### New Texture

Create a new texture.

### Remove

Delete the texture.

### Change Context

Switch to the Texture tab where you can add and edit your texture for the texture slot.

## 26.10.23 Editors - Properties Editor - Particle Properties Tab - Custom Properties panel

Grid.....	3
Invert Grid.....	3
Hexagonal Grid.....	3
Resolution.....	3
Random.....	3

## Emission Panel

The buttons in the Emission panel control the way particles are emitted over time.

### Number

The maximum amount of parent particles used in the simulation.

### Seed

Blender uses this as starting point to produce random numbers during the simulation.

### Frame Start

The start frame of particle emission. You may set negative values, which enables you to start the simulation be-

fore the actual rendering.

## End

The end frame of particle emission.

## Lifetime

The lifespan (in frames) of the particles.

## Lifetime Randomness

A random variation of the lifetime of a given particle. The shortest possible lifetime is  $\text{Lifetime} \times (1 - \text{Random})$ . Values above 1.0 are not allowed. For example with the default Lifetime value of 50 a Random setting of 0.5 will give you particles with a live span ranging from 50 frames to  $50 \times (1.0 - 0.5) = 25$  frames, and with a Random setting of 0.75 you will get particles with live spans ranging from 50 frames to  $50 \times (1.0 - 0.75) = 12.5$  frames.

## Source

### Emit From

Defines how and where the particles are emitted, giving precise control over their distribution. Defines also what content is displayed in the source sub panel.

Tip! You may use vertex groups to confine the emission, that is done in the Vertex Groups panel.

### Vertices

Emits particles from the vertices of a mesh.

### Use Modifier Stack

Take any Modifiers above the Particle Modifier in the modifier stack into account when emitting particles, else it uses the original mesh geometry.

### Random Order

The emitter element indices are gone through in a random order instead of linearly (one after the other).

### Faces & Volume

Faces emits particles from the surface of a mesh's faces.

Volume emits particles from the volume of an enclosed mesh. Your mesh must be manifold to emit particles from the volume. Some modifiers like the Edge Split Modifier break up the surface, in which case volume emission will not work correctly!

## Use Modifier Stack

Take any Modifiers above the Particle Modifier in the modifier stack into account when emitting particles, else it uses the original mesh geometry.

## Distribution

These settings control how the emissions of particles are distributed throughout the emission locations when emitting from either Faces or Volume.

### *Jittered*

#### Random Order

The emitter element indices are gone through in a random order instead of linearly (one after the other).

#### Even Distribution

Particle distribution is made even based on surface area of the elements, i.e. small elements emit less particles than large elements, so that the particle density is even.

#### Particles/Face

Number of emissions per face (0 = automatic).

#### Jittering Amount

Amount of jitter applied to the sampling.

### *Random*

#### Random Order

The emitter element indices are gone through in a random order instead of linearly (one after the other).

#### Even Distribution

Particle distribution is made even based on surface area of the elements, i.e. small elements emit less particles than large elements, so that the particle density is even.

### *Grid*

#### Invert Grid

Invert what is considered the object and what is not.

#### Hexagonal Grid

Uses a hexagonal-shaped grid instead of a rectangular one.

#### Resolution

Resolution of the grid.

#### Random

Add a random offset to grid locations.

Current Cache to Bake.....	4
Bake All Dynamics.....	4
Free All Bakes.....	5
Update All To Frame.....	5

### Cache Panel

Particle data can be cached in memory or stored on a drive. This improves real-time response and avoids unnecessary recalculation of particles. But creates also big files.

The Emitter particle system uses a unified system for caching and baking (together with Soft Body and Cloth).

Important! The file needs to be saved after baking. When the file is not saved then some options are not available.

Important! The particle settings becomes unavailable once the particle cache is baked. You need to remove the bake when you want to change the settings.

## Hints

The simulation is only calculated for positive frames in between the Start and End frames of the Cache panel, whether you bake or not. So if you want a simulation that is longer than the default frame range, you have to change the End frame.

When an animation is played, each physics system writes each frame to the cache. Note that for the cache to fill up, one has to start the playback before or on the frame that the simulation starts.

The cache is cleared automatically on changes. But not on all changes, so it may be necessary to free it manually. For example if you change a force field.

The system is protected against changes after baking. If for example the mesh changes the simulation is not calculated anew.

The bake result can be cleared by clicking on the Free Bake button in the simulation cache settings.

A simulation can only be edited in Particle Edit Mode when it has been baked in memory. And cannot be edited if the Disk Cache is used.

If you are not allowed to write to the required sub directory caching will not happen. For example if your blend-file path is very long and your operating system has a limit on the path length that is supported.

Be careful with the sequence of modifiers in the modifier stack. You may have a different number of faces in the 3D Viewport and for rendering (For example when using subdivision surface). Then the rendered result may be very different from what you see in the 3D Viewport.

## Caches List

The list of available caches. The caches have no name by default. Double click to add a name.

You can store and manage multiple caches at once for the same physics object. The active cache is the one that gets used.

## Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## *Invert*

Exclude the search term instead of searching for it.

## *Sort by Name*

Sort the List by name.

## Add New Cache

Add a new cache.

## Delete current Cache

Deletes the selected cache.

## External

Allows you to read the cache from a drive using a user-specified file path.

Note! The cache name in Caches List and the Index Number has to exactly match the external cache files name in order to work. The cache files name format is name\_frame\_index.bphys.

You can create such cache files when you tick Disk cache with External off, and save the blend file. Then the bphys files gets created in a folder besides the blend file.

## Index Number

The index number of cache files. (The last two digits of the files name.)

## File Path

Select the directory path to the cache files.

## Info string

An info string. Gives different messages, dependent of the status.

## Cache Step

The interval for storing simulation data.

Note! Some physics systems (such as particles) allow for positions to be stored only on every nth frame, letting the positions for in-between frames be interpolated. Using a cache step greater than one will result in a smaller cache, but the result may differ from the original simulation.

## Info string

An info string. Gives different messages, dependent of the status.

## Disk Cache

Save the cache externally in a folder instead inside of the blend file. The cache of a baked simulation will be stored inside the blend-file when you save it. A folder named blendcache\_[filename] will then be created along-

side the blend-file. The blend-file must be saved first and then again.

## Use Library Path

Share the disk cache when the physics object is linked into another blend-file.

When this option is enabled, linked versions of the object will reference the same disk cache. Otherwise linked versions of the object will use independent caches.

## Compression

The compression level for cached files.

### **None**

Do not compress the cache.

### **Light**

Compression will optimize the speed of compressing/decompressing operations over file size.

### **Heavy**

Compression will result in smaller cache files, but requires more CPU power to compress / decompress.

## Bake / Delete Bake

Start baking. Once you have baked the cache the button turns into a Delete bake button. And allows you to remove the bake.

The baking progress can be seen in the footer. You need to be in Object Mode to bake.

## Calculate To Frame

Bake only up to the current frame. Limited by End frame set in the cache settings.

## Current Cache to Bake

Store any temporarily cached simulation data as a bake. Note that playing the animation will try to simulate any visible physics simulations. Depending on the physics type, this data may be temporarily cached. Normally such temporary caches are cleared when an object or setting is modified, but converting it to a bake will “save” it.

## Bake All Dynamics

Bake all physics systems in the scene, even those of different types. Useful for baking complex setups involving interactions between different physics types.

## **Free All Bakes**

Free bakes of all physics systems in the scene, even those of different types.

## **Update All To Frame**

Bake all physics systems in the scene to the current frame.

## 26.10.4 Editors - Properties Editor - Particle Properties Tab - Rotation panel

### Table of content

Rotation Panel.....	1

Object X, Y, Z.....	2
Randomize.....	2
Phase.....	2
Randomize Phase.....	2
Dynamic.....	2
Angular Velocity.....	2
Axis.....	2
Amount.....	2

## Rotation Panel

Specify how the individual particles are rotated during their travel. To visualize the rotation of a particle you should choose visualization type Axis in the Visualization panel and increase the Display Size.

### Orientation Axis

Sets the initial rotation of the particle by aligning the X axis in the direction of:

#### None

The global X axis.

#### Normal

Orient to the emitter's surface normal, the objects Y axis points outwards.

#### Normal-Tangent

As with normal, orient the Y axis to the surface normal. Also orient the X axis to the tangent for control over the objects rotation about the normal. requires UV coordinates, the UV rotation effects the objects orientation, currently uses the active UV map. This allow deformation without the objects rotating in relation to their surface.

## Velocity

The particle's initial velocity.

## Global X, Y, Z

One of the global axes.

## Object X, Y, Z

One of the emitter object axes.

## Randomize

Randomizes rotation.

## Phase

Initial rotation phase.

## Randomize Phase

Adds a random variation to the Phase.

## Dynamic

If Dynamic is enabled, only initializes particles to the chosen rotation and angular velocity and let the physics simulation handle the rest. Particles then change their angular velocity if they collide with other objects (like in the real world due to friction between the colliding surfaces). Otherwise the angular velocity is predetermined at all times (i.e. set rotation to dynamic/constant).

## Angular Velocity

## Axis

Which axis to use for the angular velocity.

Hint! If you use a Curve Guide do not turn on Dynamic. Curve Follow does also not work for particles.

## Amount

The magnitude of angular velocity.

# Render Panel

The Render Panel controls how particles appear when they are rendered.

Note! Cycles supports only Object and Collection render types. Halo Line and Path are not supported.

## Render As

Render the particles with different methods.

### All render methods

#### Scale

The size of the particles.

#### Scale Randomness

Give the particles a random size.

#### Show Emitter

Render the particle emitting mesh. This does not affect the viewport rendering!

#### None

Don't render the particles.

#### Halo + Line

Line renders the particles as lines. Halo are rendered as glowing dots or a lit-

the cloud of light. Although they are not really lights because they do not cast light into the scene like a light object. They are called Halos because you can see them, but they do not have any substance.

## Material

Set which of the object's materials is used to shade the particles.

## Coordinates System

Use a different object's coordinates to determine the birth of particles.

## Extra

### Parents Particles

Render also parent particles if child particles are used. Children have a lot of different deformation options, so the straight parents would stand between their curly children. So by default Parents are not rendered if you activate Children. See Children.

### Unborn

Render particles before they are born.

### Dead

Render particles after they have died. This is very useful if particles die in a collision Die on hit, so you can cover objects with particles.

## Path

The Path visualization needs a Hair particle system or Keyed particles.

## Material

Set which of the object's materials is used to shade the particles.

## Coordinates System

Use a different object's coordinates to determine the birth of particles.

## Path subpanel

### B-Spline

Interpolate hair using B-splines. This may be an option for you if you want to use low Render values. You lose a bit of control but gain smoother paths.

### Steps

Set the number of subdivisions of the rendered paths (the value is a power of 2). You should set this value carefully, because if you increase the render value by two you need four times more memory to render. Also the rendering is faster if you use low render values (sometimes drastically). But how low you can go with this value depends on the waviness of the hair (the value is a power of 2). This means 0 steps give 1 subdivision, 1 give 2 subdivisions, 2 → 4, 3 → 8, 4 → 16, ... n → n<sup>2</sup>.

## ***Timing subpanel***

### **Absolute Path Time**

Path timing is in absolute frames.

### **End**

End time of the practical path.

### **Random**

Give the path length a random variation.

## ***Extra***

### **Parents Particles**

Render also parent particles if child particles are used. Children have a lot of different deformation options, so the straight parents would stand between their curly children. So by default Parents are not rendered if you activate Children. See Children.

### **Unborn**

Render particles before they are born.

### **Dead**

Render particles after they have died. This is very useful if particles die in a collision Die on hit, so you can cover objects with particles.

---

## **Object**

## ***Object subpanel***

### **Instance Object**

The specified object is instanced in place of each particle.

### **Global Coordinates**

Use object's global coordinates for instancing.

### **Object Rotation**

Use the rotation of the object.

### **Object Scale**

Use the size of the object.

## Extra

### Parents Particles

Render also parent particles if child particles are used. Children have a lot of different deformation options, so the straight parents would stand between their curly children. So by default Parents are not rendered if you activate Children. See Children.

### Unborn

Render particles before they are born.

### Dead

Render particles after they have died. This is very useful if particles die in a collision Die on hit, so you can cover objects with particles.

---

## Collection

### Collection subpanel

#### Instance Collection

The objects that belong to a collection are instanced sequentially in the place of the particles.

#### Whole Collection

Use the whole group at once, instead of one of its elements, the group being displayed in place of each particle.

#### Pick Random

The objects in the group are selected in a random order, and only one object is displayed in place of a particle. Please note that this mechanism fully replaces old Blender particles system using parentage and Instancing Verts to replace particles with actual geometry. This method is fully deprecated and does not work anymore.

#### Global Coordinates

Use object's global coordinates for instancing.

#### Object Rotation

Use the rotation of the objects.

#### Object Scale

Use the size of the objects.

## Use Count

Use objects multiple times in the same groups. Specify the order and number of times to repeat each object with the list view that appears.

## Dupli Object Index list

The list with the objects of the chosen instance collection.

## Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## Invert

Exclude the search term instead of searching for it.

## Sort by Name

Sort the List by name.

## Copy particle Dupliobject

Duplicate an object in the list.

## Remove particle Dupliobject

Remove a duplicate from the list.

## Refresh Dupliobjects

Refreshes the Dupli Object Index list.

## Count

The number of times this object is repeated with respect to other objects.

## Extra

### Parents Particles

Render also parent particles if child particles are used. Children have a lot of different deformation options, so the straight parents would stand between their curly children. So by default Parents are not rendered if you activate Children. See Children.

### Unborn

Render particles before they are born.

### Dead

Render particles after they have died. This is very useful if particles die in a collision Die on hit, so you can cover objects with particles.

## 26.10.6 Editors - Properties Editor - Particle Properties Tab - Emitter - Viewport Display panel

### Table of content

Viewport Display.....	1

None.....	1
Rendered.....	1
Point.....	2
Circle.....	2
Cross.....	2
Axis.....	2
Color.....	2
Fade Distance.....	2
Amount.....	2
Show Emitter.....	2
Size.....	2
Strand Steps.....	3

## Viewport Display

How to display the particles in the 3d viewport.

### Display as

How to display the particles in the viewport.

### None

Don't display particles in the viewport.

### Rendered

Display the particles as rendered.

Important! These settings are dependent of the render as mode in the Render panel, and some settings just displays in the right mode.

## Point

Display the particles as Points.

## Circle

Display the particles as circles.

## Cross

Displays each particle as a cross.

## Axis

Displays each particle as an axis widget.

## Color

What draw color to use for the particles.

## Fade Distance

With color mode Velocity and Acceleration. Maximum length of the particle color vector.

## Amount

Percentage of particles to display in the 3d viewport. Choosing a display percentage lower 100 makes dynamics inaccurate without baking.

## Show Emitter

Render the particle emitting mesh.

## Size

Shows with render method Halo. Size of particles in viewport in Blender Units.

## Strand Steps

Shows with render method With Path. How many steps paths are drawn with. The value needs to be a power of two.

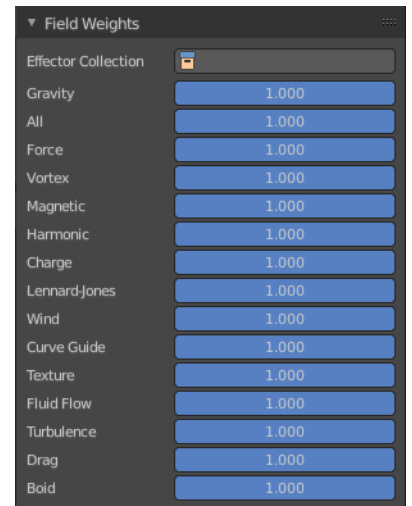

## 26.10.7 Editors - Properties Editor - Particle Properties Tab - Emitter - Field Weights panel

### Table of content

Field weights panel.....	1
Effector Collection.....	1
Gravity.....	1
All.....	1
Force, Vortex, etc.....	1

### Field weights panel

The Field Weight panel allows you to control how much influence each type of external force field, or effector, has on the particle system. Force fields are external forces that give dynamic system's motion.

### Effector Collection

Limit effectors to a specified group. Only effectors in this group will have an effect on the current system.

### Gravity

Control how much the Global Gravity has an effect on the system.

### All

Scale all of the effector weights.

### Force, Vortex, etc.

The influence for the single corresponding effector weights.

## 26.10.8 Editors - Properties Editor - Particle Properties Tab - Hair

### Table of content

Introduction..... 1  
 Workflow example..... 1

## Introduction

There are two types of particles. Emitted particles and hair. Emitted particles are used for things like fire, smoke, mist and many other animated effects. Hair is used for hair and fur effects, at characters for example.

This manual part is for particles of type Hair.

### Workflow example

Create a sphere.

Add a particle system. Change it to hair.

In the Emission panel adjust the length, etc.

Switch to Edit mode, switch to the Object Data properties tab, and create a vertex group. Assign it to a selection.

Switch back to the Particles tab. Scroll down to the Vertex Groups panel. In the Density property add the Vertex group. Now the hair should only grow at the vertex group location.

In 3D view switch to Particle Edit mode.

Start to comb the hair. Attention, when you modify the hair particles then some settings like the Emission settings are not longer available. They grey out. You would need to remove the edits to adjust these set-

tings again.

## 26.9.9 Editors - Properties Editor - Particle Properties Tab - Hair - Emission Panel

### Table of content

Emission Panel.....	1
Number.....	1

Random Order.....	3
Even Distribution.....	3
Grid.....	3
Invert Grid.....	3
Hexagonal Grid.....	3
Resolution.....	3
Random.....	3

## Emission Panel

The buttons in the Emission panel control the way particles are emitted over time.

### Number

The amount of hair strands.

### Seed

Blender uses this as starting point to produce random numbers during the simulation.

### Hair Length

Controls the length of the hair.

## Segments

How much segments each hair should have.

## Source

### Emit From

Defines how and where the particles are emitted, giving precise control over their distribution. Defines also what content is displayed in the source sub panel.

Tip! You may use vertex groups to confine the emission, that is done in the Vertex Groups panel.

### Vertices

Emits particles from the vertices of a mesh.

### Use Modifier Stack

Take any Modifiers above the Particle Modifier in the modifier stack into account when emitting particles, else it uses the original mesh geometry.

### Random Order

The emitter element indices are gone through in a random order instead of linearly (one after the other).

### Faces & Volume

Faces emits particles from the surface of a mesh's faces.

Volume emits particles from the volume of an enclosed mesh. Your mesh must be manifold to emit particles from the volume. Some modifiers like the Edge Split Modifier break up the surface, in which case volume emission will not work correctly!

### Use Modifier Stack

Take any Modifiers above the Particle Modifier in the modifier stack into account when emitting particles, else it uses the original mesh geometry.

### Distribution

These settings control how the emissions of particles are distributed throughout the emission locations when emitting from either Faces or Volume.

### Jittered

### Random Order

The emitter element indices are gone through in a random order instead of lin-

early (one after the other).

### **Even Distribution**

Particle distribution is made even based on surface area of the elements, i.e. small elements emit less particles than large elements, so that the particle density is even.

### **Particles/Face**

Number of emissions per face (0 = automatic).

### **Jittering Amount**

Amount of jitter applied to the sampling.

### **Random**

#### **Random Order**

The emitter element indices are gone through in a random order instead of linearly (one after the other).

### **Even Distribution**

Particle distribution is made even based on surface area of the elements, i.e. small elements emit less particles than large elements, so that the particle density is even.

### **Grid**

#### **Invert Grid**

Invert what is considered the object and what is not.

#### **Hexagonal Grid**

Uses a hexagonal-shaped grid instead of a rectangular one.

#### **Resolution**

Resolution of the grid.

#### **Random**

Add a random offset to grid locations.

## Intruduction

A particle system is used to animate lots of small objects at once. Particles. Each particle can be a point or a mesh, and can be joined or dynamic. They may react to different forces and influences. And they can have a life span.

There are two types of particles. Emitted particles and hair. Emitted particles are used for things like fire, smoke, mist and many other animated effects. Hair is used for hair effects, at characters for example. Some settings are the same for both types. These chapters are unioned. But each has also its own set of tools. These chapters are separated.

Particles uses a regular mesh object as the emitter. Other object types does not have the particle tab.

## Particle Modifier

When you create a particle system then a particle modifier gets added in the Modifiers panel. This works also the other way around. You can also add a particle modifier in the modifier tab. The settings remains in the particles tab.

## Workflow

Create a mesh.

Create one or more Particle Systems to emit from the mesh.

Choose the particle system type. Emit or Hair.

Go through the particle settings to adjust the Particle System settings to achieve the desired effect.

For Hair particle systems, switch to particle edit mode, and comb the emitter's flow.

To see the effect for emitted particles press play.

## Header

### List of Particle Systems

A list of the particle systems for this object. Double clicking allows to rename it.

### Realtime

Display the particle system in the viewport.

### Render

Display the particle system in the rendered result.

### Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

### Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

### *Invert*

Exclude the search term instead of searching for it.

### *Sort by Name*

Sort the List by name.

### Add Particle System Slot

Adds a new particle system.

### Remove Particle System Slot

Remove the particle system.

### Particle Specials

#### Copy Active to Selected Objects

Copies the active particle system to all selected objects.

#### Copy All to Selected Objects

Copies all particle systems from the active object to all selected objects.

#### Duplicate Particle Systems

Duplicates the particle system within the active object. The Duplicate Settings option (in the Adjust Last

Operation panel) will duplicate settings as well, so the new particle system uses its own settings.

## Particle property

### Particle settings browser

A particle settings browser with the available particle systems in the scene.

### Edit Box

The name of the currently active palette. You can also rename the palette here. A click into the edit box makes the name editable.

### Fake User

Fake User sets the element to have a fake user. Data without a user is normally not saved. But sometimes you want to force the data to be kept even when the data block has no user.

## New Particle Settings

Add a new particle system.

## Remove Particle Settings

Removes the particle system as the active particle system. Note that the particle system is still in the list.

## Type

Main selector of the system type.

Note that some of the panels are identical for both particle types. But some not. Even when they have the same label.

### Emitter

Emitter type. Particles are emitted from the object.

### Hair

Hair type, rendered as strands.

### Regrow

Type Hair. Regrows the hair for each frame. This is useful when you are animating properties.

### Advanced

Type Hair. Enables advanced settings, and reveals some more functionality. Which reflect the same ones as working in Emitter mode.

### Delete Edit

Appears when you modify the particles in particle edit mode. Resets the

particle system to the default state before combing.

### ***Disconnect Hair***

Appears when you modify the particles in particle edit mode. Disconnect the selected hair from the emitter object.

### ***Disconnect All***

Appears when you modify the particles in particle edit mode. Disconnect the whole hair from the emitter object.

## Visual Effects

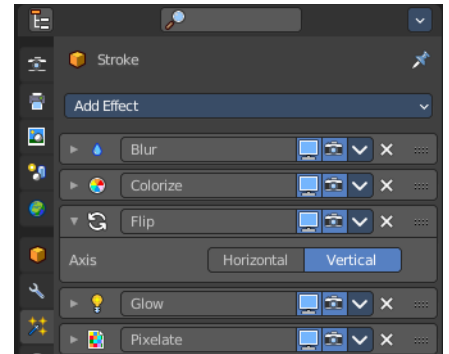

Visual Effects are for the Grease Pencil object only.

In the viewport you can apply so called visual effects to Grease pencil strokes. Like a pixelate effect.

The effect is applied to the whole image in the viewport. But just to the grease pencil object that has the effect applied. Other grease pencil objects will not be affected.

The effects renders to file. But visual effects are mainly meant for preview purposes, to judge how the result could look like after compositing. The compositing nodes are more accurate.

Visual Effects works with all renderers. Cycles, Workbench and Eevee.

You need to be in the viewport shading mode rendered. The effect does not show in material preview mode.

The effects are dependant of zoom and orientation of the viewport camera.

## General functionality

### Add

To add an effect to a grease pencil object, simply open the drop down menu, and choose the type of modifier that you want to add.

This will add the effect to the list.

## Header elements

You might want to remove an effect. Or just see the effect in the final rendering. This can be adjusted in the header. The header is what you see when you collapse the effects panel.

Elements are explained from left to right.

---

## Collapse panel

The whole modifier panel can be collapsed. Click at the arrow button up left in the header.

## Effect Icon

This icon shows the type of the effect. And has no further functionality.

## Effect Name

The name of the modifier. You can rename effects by clicking into the edit field and change the text.

## Realtime

Display the modifier in the viewport.

---

## Render

Display the modifier in the rendered result.

---

## Header menu

### ***Duplicate***

Duplicates the modifier, and places the duplicate below the current modifier.

### ***Move to first***

Move the modifier to the first position in the stack.

### ***Move to last***

Move the modifier to the last position in the stack.

## Remove

Removes the modifier from the stack.

---

## Change Context

Some modifiers cannot be removed from the modifiers stack directly. Like fluid modifiers. You need to remove the fluid simulation instead, in the physics tab. With the change context button you jump to the required tab where you can now remove the simulation.

---

## Reorder

You can have more than one modifier in the list. And sometimes the order of the modifiers is very important.

Grab the handler at the right and drag the modifier to the position where you want it to have.

## Animate Property

Some of the properties can be animated. Click at the animate property button at the right to add a keyframe.

---

## Blur

Applies a Gaussian blur to the object.

### Samples

Number of Blur samples (0 disabled the blur effect).

### Use Depth of Field

When enabled, the blur effect uses the focal plane distance of the actual camera to simulate a depth of field effect. Only available in camera view.

### Size X / Y

The blur factor in x and y direction

## Rotation

Rotation of the effect.

## Colorize

Applies colorizing effects to the object.

### Mode

#### Grayscale

Converts to a grayscale image.

#### Sepia

Converts to a sepia tone image.

#### Duotone

Converts to a black and white posterize image with high contrast and brightness.

#### Transparent

Add color transparency.

### Factor

Controls the mix value (0 fully transparent, 1 fully opaque).

### Custom

Allows to define a tint custom color.

### Color

Sets the tint color.

### Factor

How strong the effect is applied.

## Flip

Shows the object flipped horizontally and/or vertically.

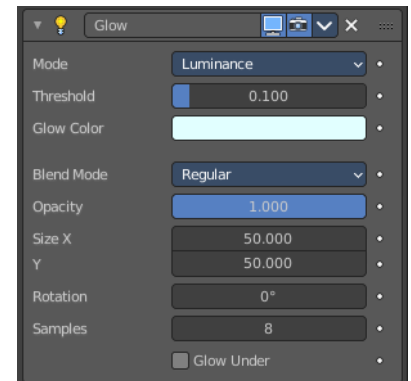

## Axis

The axis to use for the flipping.

## Glow

Adds a glowing rim around the object.

### Mode

The mode of the glow effect.

### Luminance

The glow light illuminates the entire object.

### Color

The glow light only affect a single color.

### Glow Color

Defines the glow color.

### Blend Mode

How to blend the glow with the image.

### Opacity

### Size X / Y

The size of the effect.

### Rotation

Rotation of the effect.

## Samples

Number of blur samples.

## Glow Under

Glow only affects alpha areas. Does not work with the blend mode Regular.

## Pixelate

Pixelates the grease pencil stroke.

### Size X / Y

The size of the pixels.

## Antialiasing

Use antialiasing.

## Rim

Shows a simulated rim light on the object contour.

For simulating the rim light, a masked color silhouette of the object is displaced in horizontal and/or vertical direction.

### Rim Color

The color of the rim light.

### Mask Color

Defines a color to keep unaltered.

### Blend Mode

How to blend the rimlight with the image.

### Offset X / Y

Color mask displacement in pixels along the X and Y axis.

## Blur subpanel

### Blur X / Y

The blur scale in pixels on the X and Y axis.

### Samples

Number of blur samples. A value of 0 disables the blur effect.

## Shadow

Shows a simulated shadow casted by the object.

### Shadow Color

Defines the shadow color.

### Offset X / Y

The shadow displacement in pixels along the X and Z axis.

### Scale X / Y

Scales the size of the shadow along the X and y axis.

### Rotation

The shadow rotation around the Grease Pencil object. You can use the center of the grease pencil object. With Object Pivot enabled you can also choose the pivot of another object.

### Object Pivot

Use the pivot of another object for rotation. You need to pick another object from the scene.

## Blur subpanel

### Blur X / Y

The blur scale in pixels on the X and Y axis.

### Samples

Number of blur samples. A value of 0 disables the blur effect.

## Wave Effect subpanel

Apply a wave distortion to the shadow.

### Orientation

Sets a horizontal or vertical direction for the waves.

### Amplitude

Controls the strength and the depth of the wave.

### Period

Controls the wave period. The time it takes to complete one cycle.

### Phase

Shifts the wave pattern over the shadow.

## Swirl

Applies a swirling pattern to the grease pencil object. The effect uses another object as the center of the swirl. An empty for example.

### Object

Pick the object that you want to use as the center of the swirl.

### Radius

External radius size of the swirl. The needed radius depends of camera zoom.

### Angle

Rotation angle of the swirl. A value of 0 shows no swirl.

## Wave Distortion

Adds a wave distortion to the grease pencil object.

### Orientation

Sets a horizontal or vertical direction for the waves.

## **Amplitude**

Controls the strength and the depth of the wave.

## **Period**

Controls the wave period. The time it takes to complete one cycle.

## **Phase**

Shifts the wave pattern over the grease pencil object.

## Force Fields panel

Force Fields offer a way to add extra movement to dynamic systems like Particles, Soft Bodies, Rigid Bodies and Cloth objects.

Note that when you work with particles, softbody or cloth system and change one of the force fields parameters, then you need to recalculate the particles, softbody or cloth systems.

### Type

There are several force field types available.

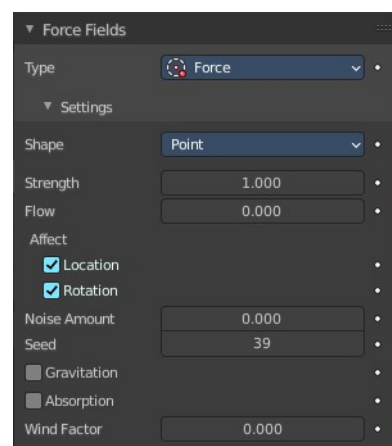

## Type Force

A Force type force field gives a constant force towards (positive strength) or away from (negative strength) the object's center.

For Boids a field with positive strength can be used as a Goal. A field with negative strength can be used as Predator. Whether Boids seek or fly goals/predators depends on the Physics settings of the Boids.

## Settings subpanel

### Shape

The direction that is used to calculate the effector force.

### Strength

The strength of the force.

### Flow / Inflow

Convert effector force into air force velocity / Inwards component of the force.

### Affect

#### *Location*

Affect the location of the particles.

#### *Rotation*

Affect the rotation of the particles.

### Noise Amount

Amount of noise for the force effect.

### Seed

The random seed for the noise amount.

## Gravitation

Multiply force by 1 divided through the distance in square.

## Absorption

Force gets absorbed by collision objects.

## Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

## Falloff Subpanel

## Shape

### *Sphere*

Falloff is uniform in all directions, as in a sphere.

### *Tube*

Fall off results in a tube shaped force field. The Field's Radial falloff can be adjusted, as well as the Minimum and Maximum distances of the field.

### *Cone*

Fall off results in a cone shaped force field. Additional options are the same as those of Tube options.

## Z Direction

Fall-off can be set to apply only in the direction of the positive Z Axis, negative Z Axis, or both.

### *Power (Power)*

How the power of the force field changes with the distance from the force field. If  $r$  is the distance from the center of the object, the force changes with  $1/r^{\text{Power}}$ . A Fall-off of 2 changes the force field with  $1/r^2$ , which is the falloff of gravitational pull.

### *Min Distance*

The distance from the object center, up to where the force field is effective with full strength. If you have a Fall-off of 0 this parameter does nothing, because the field is effective with full strength up to Max Dist (or the infinity). Shown by an additional circle around the object.

## **Max Distance**

Makes the force field only take effect within a specified maximum radius (shown by an additional circle around the object).

# Type Wind

Constant force along the Z axis.

## **Settings Subpanel**

## **Shape**

The direction that is used to calculate the effector force.

## **Strength**

The strength of the force.

## **Flow / Inflow**

Convert effector force into air force velocity / Inwards component of the force.

## **Affect**

### **Location**

Affect the location of the particles.

### **Rotation**

Affect the rotation of the particles.

## **Noise Amount**

Amount of noise for the force effect.

## **Seed**

The random seed for the noise amount.

## **Absorption**

Force gets absorbed by collision objects.

## Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

## Falloff Subpanel

## Shape

### *Sphere*

Falloff is uniform in all directions, as in a sphere.

### *Tube*

Fall off results in a tube shaped force field. The Field's Radial falloff can be adjusted, as well as the Minimum and Maximum distances of the field.

### *Cone*

Fall off results in a cone shaped force field. Additional options are the same as those of Tube options.

## Z Direction

Fall-off can be set to apply only in the direction of the positive Z Axis, negative Z Axis, or both.

### *Power (Power)*

How the power of the force field changes with the distance from the force field. If  $r$  is the distance from the center of the object, the force changes with  $1/r^{\text{Power}}$ . A Fall-off of 2 changes the force field with  $1/r^2$ , which is the falloff of gravitational pull.

### *Min Distance*

The distance from the object center, up to where the force field is effective with full strength. If you have a Fall-off of 0 this parameter does nothing, because the field is effective with full strength up to Max Dist (or the infinity). Shown by an additional circle around the object.

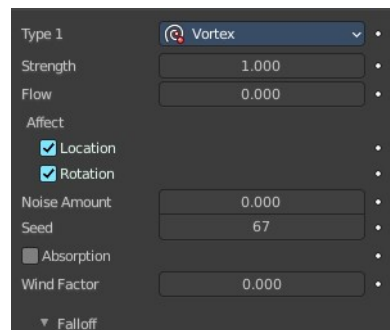

### *Max Distance*

Makes the force field only take effect within a specified maximum radius (shown by an additional circle around the object).

## Type Vortex

Spiraling force that twists the force object's local Z axis. Use case could be a tornado for example.

### Settings Subpanel

### Shape

The direction that is used to calculate the effector force.

### Strength

The strength of the force.

### Flow / Inflow

Convert effector force into air force velocity / Inwards component of the force.

### Affect

#### *Location*

Affect the location of the particles.

#### *Rotation*

Affect the rotation of the particles.

### Noise Amount

Amount of noise for the force effect.

### Seed

The random seed for the noise amount.

### Absorption

Force gets absorbed by collision objects.

### Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

## Falloff Subpanel

### Shape

#### ***Sphere***

Falloff is uniform in all directions, as in a sphere.

#### ***Tube***

Fall off results in a tube shaped force field. The Field's Radial falloff can be adjusted, as well as the Minimum and Maximum distances of the field.

#### ***Cone***

Fall off results in a cone shaped force field. Additional options are the same as those of Tube options.

### Z Direction

Fall-off can be set to apply only in the direction of the positive Z Axis, negative Z Axis, or both.

#### ***Power (Power)***

How the power of the force field changes with the distance from the force field. If  $r$  is the distance from the center of the object, the force changes with  $1/r^{\text{Power}}$ . A Fall-off of 2 changes the force field with  $1/r^2$ , which is the falloff of gravitational pull.

#### ***Min Distance***

The distance from the object center, up to where the force field is effective with full strength. If you have a Fall-off of 0 this parameter does nothing, because the field is effective with full strength up to Max Dist (or the infinity). Shown by an additional circle around the object.

#### ***Max Distance***

Makes the force field only take effect within a specified maximum radius (shown by an additional circle around the object).

## Type Magnetic

A magnetic force field simulates the force of magnetism on magnetized objects.

### Settings Subpanel

#### Shape

The direction that is used to calculate the effector force.

#### Strength

The strength of the force.

#### Flow

Convert effector force into air force velocity.

#### Affect

##### *Location*

Affect the location of the particles.

##### *Rotation*

Affect the rotation of the particles.

#### Noise Amount

Amount of noise for the force effect.

#### Seed

The random seed for the noise amount.

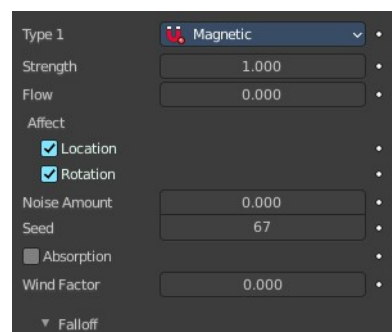

#### Absorption

Force gets absorbed by collision objects.

#### Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

### Falloff Subpanel

## Shape

### Sphere

Falloff is uniform in all directions, as in a sphere.

### Tube

Fall off results in a tube shaped force field. The Field's Radial falloff can be adjusted, as well as the Minimum and Maximum distances of the field.

### Cone

Fall off results in a cone shaped force field. Additional options are the same as those of Tube options.

## Z Direction

Fall-off can be set to apply only in the direction of the positive Z Axis, negative Z Axis, or both.

### Power (Power)

How the power of the force field changes with the distance from the force field. If  $r$  is the distance from the center of the object, the force changes with  $1/r^{\text{Power}}$ . A Fall-off of 2 changes the force field with  $1/r^2$ , which is the falloff of gravitational pull.

### Min Distance

The distance from the object center, up to where the force field is effective with full strength. If you have a Fall-off of 0 this parameter does nothing, because the field is effective with full strength up to Max Dist (or the infinity). Shown by an additional circle around the object.

### Max Distance

Makes the force field only take effect within a specified maximum radius (shown by an additional circle around the object).

## Type Harmonic

The source of this force field is the zero point of a harmonic oscillator. If you set the *Damping* parameter to 1, the movement is stopped in the moment the object is reached.

## Settings Subpanel

## Shape

The direction that is used to calculate the effector force.

## Strength

The strength of the force.

## Damping

Damping of the harmonic force.

## Rest Length

The rest length of the harmonic force.

## Affect

### *Location*

Affect the location of the particles.

### *Rotation*

Affect the rotation of the particles.

## Noise Amount

Amount of noise for the force effect.

## Seed

The random seed for the noise amount.

## Multiple Springs

Every point is effected by multiple springs.

## Absorption

Force gets absorbed by collision objects.

## Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

## Falloff Subpanel

## Shape

### ***Sphere***

Falloff is uniform in all directions, as in a sphere.

### **Tube**

Fall off results in a tube shaped force field. The Field's Radial falloff can be adjusted, as well as the Minimum and Maximum distances of the field.

### **Cone**

Fall off results in a cone shaped force field. Additional options are the same as those of Tube options.

### **Z Direction**

Fall-off can be set to apply only in the direction of the positive Z Axis, negative Z Axis, or both.

### **Power (Power)**

How the power of the force field changes with the distance from the force field. If  $r$  is the distance from the center of the object, the force changes with  $1/r^{\text{Power}}$ . A Fall-off of 2 changes the force field with  $1/r^2$ , which is the falloff of gravitational pull.

### **Min Distance**

The distance from the object center, up to where the force field is effective with full strength. If you have a Fall-off of 0 this parameter does nothing, because the field is effective with full strength up to Max Dist (or the infinity). Shown by an additional circle around the object.

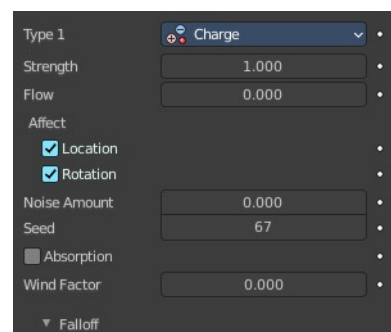

### **Max Distance**

Makes the force field only take effect within a specified maximum radius (shown by an additional circle around the object).

## Type Charge

Special force field based on the charge of particles. Charge force fields just affects other charge force fields.

### **Settings Subpanel**

## Shape

The direction that is used to calculate the effector force.

## Strength

The strength of the force.

## Flow

Convert effector force into air force velocity.

## Affect

### *Location*

Affect the location of the particles.

### *Rotation*

Affect the rotation of the particles.

## Noise Amount

Amount of noise for the force effect.

## Seed

The random seed for the noise amount.

## Absorption

Force gets absorbed by collision objects.

## Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

## Falloff Subpanel

## Shape

### *Sphere*

Falloff is uniform in all directions, as in a sphere.

### *Tube*

Fall off results in a tube shaped force field. The Field's Radial falloff can be adjusted, as well as the Minimum and Maximum distances of the field.

## Cone

Fall off results in a cone shaped force field. Additional options are the same as those of Tube options.

## Z Direction

Fall-off can be set to apply only in the direction of the positive Z Axis, negative Z Axis, or both.

## Power (Power)

How the power of the force field changes with the distance from the force field. If  $r$  is the distance from the center of the object, the force changes with  $1/r^{\text{Power}}$ . A Fall-off of 2 changes the force field with  $1/r^2$ , which is the falloff of gravitational pull.

## Min Distance

The distance from the object center, up to where the force field is effective with full strength. If you have a Fall-off of 0 this parameter does nothing, because the field is effective with full strength up to Max Dist (or the infinity). Shown by an additional circle around the object.

## Max Distance

Makes the force field only take effect within a specified maximum radius (shown by an additional circle around the object).

# Type Lennard Jones

Force field based on the Lennard-Jones potential. The Lennard-Jones potential describes the interactions of two neutral particles using a relatively simple mathematical model. At a distance smaller than the combined sizes the field is very repulsive and after that distance it's attractive.

Particles can have for example both a charge and a Lennard-Jones potential.

## Settings Subpanel

### Shape

The direction that is used to calculate the effector force.

### Strength

The strength of the force.

### Flow

Convert effector force into air force velocity.

## Affect

### Location

Affect the location of the particles.

### Rotation

Affect the rotation of the particles.

### Noise Amount

Amount of noise for the force effect.

### Seed

The random seed for the noise amount.

### Absorption

Force gets absorbed by collision objects.

### Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

## Falloff Subpanel

### Shape

#### *Sphere*

Falloff is uniform in all directions, as in a sphere.

#### *Tube*

Fall off results in a tube shaped force field. The Field's Radial falloff can be adjusted, as well as the Minimum and Maximum distances of the field.

#### *Cone*

Fall off results in a cone shaped force field. Additional options are the same as those of Tube options.

### Z Direction

Fall-off can be set to apply only in the direction of the positive Z Axis, negative Z Axis, or both.

### Power (Power)

How the power of the force field changes with the distance from the force field. If  $r$  is the distance from the

center of the object, the force changes with  $1/r^{\text{Power}}$ . A Fall-off of 2 changes the force field with  $1/r^2$ , which is the falloff of gravitational pull.

### **Min Distance**

The distance from the object center, up to where the force field is effective with full strength. If you have a Fall-off of 0 this parameter does nothing, because the field is effective with full strength up to Max Dist (or the infinity). Shown by an additional circle around the object.

### **Max Distance**

Makes the force field only take effect within a specified maximum radius (shown by an additional circle around the object).

## Type Texture

Adds a force field based on a texture. The force in the 3 directions is color coded.

Red is coding for the x-axis, green for the y-axis and blue for the z-axis. A value of 0.5 means no force, a value larger than 0.5 acceleration in negative axis direction (like -Z), a value smaller than 0.5 acceleration in positive axis direction (like +Z).

## Settings Subpanel

### **Texture mode**

This sets the way a force vector is derived from the texture.

#### **RGB**

Uses the color components directly as the force vector components in the color encoded directions. You need an RGB texture for this, e.g. an image or a color band. So a Blend texture without a color band would not suffice.

#### **Gradient**

Calculates the force vector as the 3d-gradient of the intensity (greyscale) of the texture. The gradient vector always points to the direction of increasing brightness.

#### **Curl**

Calculates the force vector from the curl of the 3d-rgb texture (rotation of rgb vectors). This also works only with a color texture. It can be used for example to create a nice looking turbulence force with a color clouds texture with Perlin noise.

## Strength

The strength of the force.

## Affect

### *Location*

Affect the location of the particles.

## Nabla

It is the offset used to calculate the partial derivatives needed for Gradient and Curl texture modes.

## Use Coordinates

Uses the emitter object coordinates as the texture space the particles use.

## 2D

Apply force only in 2D.

## Texture Sub Subpanel

### *Texture Property*

### Texture Browser

A list of the available textures in the scene.

### *Name*

The name of the currently active texture. You can rename the texture here by clicking at the edit box.

### Fake User

Keep this texture in the scene even if it has no user.

### New Texture

Add a new texture.

### Remove

Remove the texture.

### Show Texture in Texture Tab

Jumps to the texture tab where you can edit your texture.

## Falloff Subpanel

## Shape

### **Sphere**

Falloff is uniform in all directions, as in a sphere.

### **Tube**

Fall off results in a tube shaped force field. The Field's Radial falloff can be adjusted, as well as the Minimum and Maximum distances of the field.

### **Cone**

Fall off results in a cone shaped force field. Additional options are the same as those of Tube options.

### **Z Direction**

Fall-off can be set to apply only in the direction of the positive Z Axis, negative Z Axis, or both.

### **Power (Power)**

How the power of the force field changes with the distance from the force field. If  $r$  is the distance from the center of the object, the force changes with  $1/r^{\text{Power}}$ . A Fall-off of 2 changes the force field with  $1/r^2$ , which is the falloff of gravitational pull.

### **Min Distance**

The distance from the object center, up to where the force field is effective with full strength. If you have a Fall-off of 0 this parameter does nothing, because the field is effective with full strength up to Max Dist (or the infinity). Shown by an additional circle around the object.

### **Max Distance**

Makes the force field only take effect within a specified maximum radius (shown by an additional circle around the object).

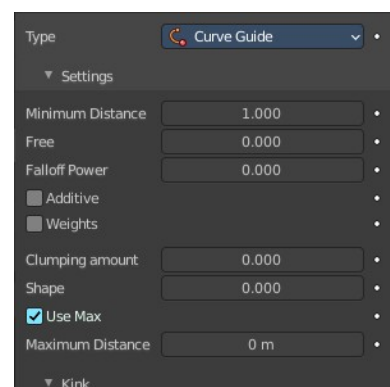

## Type Curve Guide

Creates a force along a curve object.

A typical scenario would be to move a red blood cell inside a vein, or to animate the particle flow in a motor. You can use Curve Guide s also to shape certain hair strands.

Note! You can also use the Particle Mode to define a path.

The option Curve Follow does not work for particles. Instead you have to set Angular Velocity in the Physics panel of the Particle sub-context to Spin and leave the rotation constant. For example don't turn on Dynamic.

Curve Guides affect all particles on the same layer, independently from their distance to the curve. If you have several guides in a layer, their fields add up to each other (the way you may have learned it in your physics course). But you can limit their influence radius by changing their Minimum Distance (see below).

Note! The Curve Guide does not effect Softbodies.

## Settings subpanel

### Minimum Distance

The distance from the curve, up to where the force field is effective with full strength. If you have a Fall-off of 0 this parameter does nothing, because the field is effective with full strength up to MaxDist (or the infinity). MinDist is shown with a circle at the endpoints of the curve in the 3D window.

### Free

Fraction of particle life time, that is not used for the curve.

### Falloff Power

How quickly strength falls off with distance from the force field. A Fall-off of 1 means a linear progression.

### Additive

If you use Additive, the speed of the particles is also evaluated depending on the Fall-off.

### Weights

Use Curve weights to influence the particle influence along the curve.

### Clumping Amount

The particles come together at the end of the curve (1) or they drift apart (-1).

### Shape

Defines the form in which the particles come together. +0.99: the particles meet at the end of the curve. 0: linear progression along the curve. -0.99: the particles meet at the beginning of the curve.

### Use Max

The maximum influence radius. Shown by an additional circle around the curve object.

The other settings govern the form of the force field along the curve.

## Kink sub subpanel

Kink changes the shape that the particles can take. It adds an offset.

## Type

### Curl

The radius of the influence depends on the distance of the curve to the emitter.

### Radial

A three dimensional, standing wave.

### Wave

A two dimensional, standing wave.

### Braid

Braid.

### Roll

A one dimensional, standing wave.

### Axis

Which axis to use for the offset.

### Frequency

The frequency of the offset.

### Shape

Adjust the offset to the beginning/end.

### Amplitude

The Amplitude of the offset.

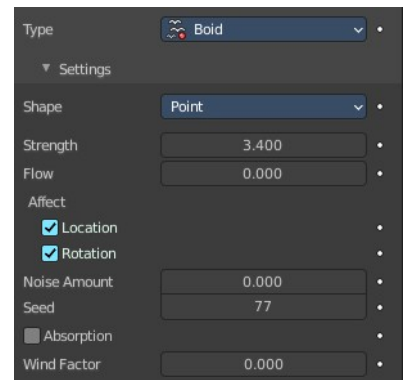

## Type Boid

Creates a force that acts as a boid's predator or target. Boids simulates the flocking behavior of birds.

## Settings Subpanel

### Shape

The direction that is used to calculate the effector force.

## Strength

The strength of the force.

## Flow

Convert effector force into air force velocity.

## Affect

### *Location*

Affect the location of the particles.

### *Rotation*

Affect the rotation of the particles.

## Noise Amount

Amount of noise for the force effect.

## Seed

The random seed for the noise amount.

## Absorption

Force gets absorbed by collision objects.

## Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

## Falloff Subpanel

## Shape

### *Sphere*

Falloff is uniform in all directions, as in a sphere.

### *Tube*

Fall off results in a tube shaped force field. The Field's Radial falloff can be adjusted, as well as the Minimum and Maximum distances of the field.

## Cone

Fall off results in a cone shaped force field. Additional options are the same as those of Tube options.

## Z Direction

Fall-off can be set to apply only in the direction of the positive Z Axis, negative Z Axis, or both.

## Power (Power)

How the power of the force field changes with the distance from the force field. If  $r$  is the distance from the center of the object, the force changes with  $1/r^{\text{Power}}$ . A Fall-off of 2 changes the force field with  $1/r^2$ , which is the falloff of gravitational pull.

## Min Distance

The distance from the object center, up to where the force field is effective with full strength. If you have a Fall-off of 0 this parameter does nothing, because the field is effective with full strength up to Max Dist (or the infinity). Shown by an additional circle around the object.

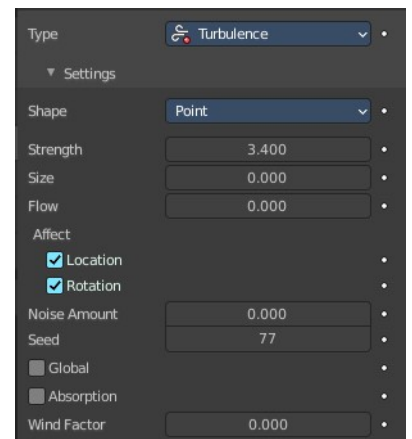

## Max Distance

Makes the force field only take effect within a specified maximum radius (shown by an additional circle around the object).

# Type Turbulence

Create turbulence with a noise field. This creates a random and chaotic 3D noise effect.

## Settings Subpanel

## Shape

The direction that is used to calculate the effector force.

## Strength

The strength of the force.

## Size

The size of the turbulence.

## Flow

Convert effector force into air force velocity.

## Affect

### *Location*

Affect the location of the particles.

### *Rotation*

Affect the rotation of the particles.

## Noise Amount

Amount of noise for the force effect.

## Seed

The random seed for the noise amount.

## Global

Use global coordinates for the turbulence.

## Absorption

Force gets absorbed by collision objects.

## Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

## Falloff Subpanel

## Shape

### *Sphere*

Falloff is uniform in all directions, as in a sphere.

### *Tube*

Fall off results in a tube shaped force field. The Field's Radial falloff can be adjusted, as well as the Minimum and Maximum distances of the field.

## Cone

Fall off results in a cone shaped force field. Additional options are the same as those of Tube options.

## Z Direction

Fall-off can be set to apply only in the direction of the positive Z Axis, negative Z Axis, or both.

## Power (Power)

How the power of the force field changes with the distance from the force field. If  $r$  is the distance from the center of the object, the force changes with  $1/r^{\text{Power}}$ . A Fall-off of 2 changes the force field with  $1/r^2$ , which is the falloff of gravitational pull.

## Min Distance

The distance from the object center, up to where the force field is effective with full strength. If you have a Fall-off of 0 this parameter does nothing, because the field is effective with full strength up to Max Dist (or the infinity). Shown by an additional circle around the object.

## Max Distance

Makes the force field only take effect within a specified maximum radius (shown by an additional circle around the object).

# Type Drag

Create a force that dampens motion. The particles motion is slowing down.

## Settings Subpanel

## Shape

The direction that is used to calculate the effector force.

## Linear

Drag component proportional to velocity.

## Quadratic

Drag component proportional to square velocity.

## Affect

### Location

Affect the location of the particles.

### Rotation

Affect the rotation of the particles.

### Noise Amount

Amount of noise for the force effect.

### Seed

The random seed for the noise amount.

### Absorption

Force gets absorbed by collision objects.

### Wind Factor

How much the force is reduced when acting parallel to a surface. Like a cloth.

## Falloff Subpanel

### Shape

#### Sphere

Falloff is uniform in all directions, as in a sphere.

#### Tube

Fall off results in a tube shaped force field. The Field's Radial falloff can be adjusted, as well as the Minimum and Maximum distances of the field.

#### Cone

Fall off results in a cone shaped force field. Additional options are the same as those of Tube options.

### Z Direction

Fall-off can be set to apply only in the direction of the positive Z Axis, negative Z Axis, or both.

## Power (*Power*)

How the power of the force field changes with the distance from the force field. If  $r$  is the distance from the center of the object, the force changes with  $1/r^{\text{Power}}$ . A Fall-off of 2 changes the force field with  $1/r^2$ , which is the falloff of gravitational pull.

## Min Distance

The distance from the object center, up to where the force field is effective with full strength. If you have a Fall-off of 0 this parameter does nothing, because the field is effective with full strength up to Max Dist (or the infinity). Shown by an additional circle around the object.

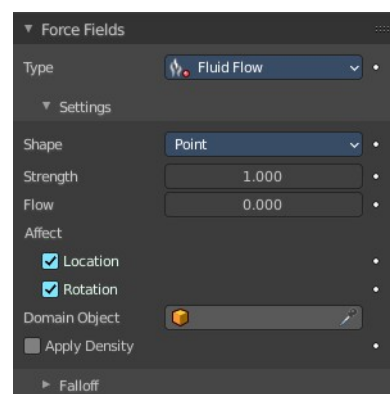

## Max Distance

Makes the force field only take effect within a specified maximum radius (shown by an additional circle around the object).

# Type Fluid Flow

Create a force field based on fluid simulation velocities.

## Settings Subpanel

## Shape

The direction that is used to calculate the effector force.

## Strength

The strength of the force.

## Flow

Convert effector force into air force velocity.

## Affect

### Location

Affect the location of the particles.

### Rotation

Affect the rotation of the particles.

## Domain Object

Select Domain object of the smoke simulation.

## Apply Density

Adjust force strength based on smoke density.

## Falloff Subpanel

### Shape

#### **Sphere**

Falloff is uniform in all directions, as in a sphere.

#### **Tube**

Fall off results in a tube shaped force field. The Field's Radial falloff can be adjusted, as well as the Minimum and Maximum distances of the field.

#### **Cone**

Fall off results in a cone shaped force field. Additional options are the same as those of Tube options.

### Z Direction

Fall-off can be set to apply only in the direction of the positive Z Axis, negative Z Axis, or both.

#### **Power (Power)**

How the power of the force field changes with the distance from the force field. If  $r$  is the distance from the center of the object, the force changes with  $1/r^{\text{Power}}$ . A Fall-off of 2 changes the force field with  $1/r^2$ , which is the falloff of gravitational pull.

#### **Min Distance**

The distance from the object center, up to where the force field is effective with full strength. If you have a Fall-off of 0 this parameter does nothing, because the field is effective with full strength up to Max Dist (or the infinity). Shown by an additional circle around the object.

#### **Max Distance**

Makes the force field only take effect within a specified maximum radius (shown by an additional circle around the object).

## Collision

Collision sets the mesh object as a static collider. Particles, Soft Bodies and Cloth objects may collide with mesh objects. Boids try to avoid Collision objects.

Once you add a collision to a mesh a modifier gets created in the modifier properties tab. Here you can add other modifiers that may interact with the collision. But the collision settings are just accessible from the physics tab.

### Hints!

You may limit the effect on particles to a group of objects. This can be done in the Field Weights panel in the particles tab of the object with the particles.

Make sure that the normals of the mesh surface are facing towards the particles/points for correct deflection.

Hair particles react directly to force fields, so if you use a force field with a short range you do not need necessarily collision.

Hair particles avoid their emitting mesh if you edit them in Particle Edit Mode. So you can at least model the hair with collision.

Hair particles ignore deflecting objects. But you can animate them as soft bodies which take deflection into account.

Soft body collisions can make problems if one of the objects move too fast. Then the soft body will penetrate the mesh.

If you change the deflection settings for an object you have to recalculate the particle, soft body or cloth system by Delete Bake, this is not done automatically.

## Field Absorption

A deflector can also deflect effectors. You can specify some collision/deflector objects which deflect a specific portion of the effector force using the Field Absorption value. 100% absorption results in no force getting through the collision/deflector object at all. If you have three collision object behind each other with e.g. 10%, 43% and 3%, the absorption ends up at around 50%  $100 \times (1-0.1) \times (1-0.43) \times (1-0.03)$ .

## Particle subpanel

### Permeability

Fraction of particles passing through the mesh.

### Stickiness

How much particles stick to the object.

### Kill Particles

Deletes Particles upon impact.

### Damping

Damping during a collision (independent of the velocity of the particles).

### Randomize

Random variation of damping.

### Friction

Friction during movements along the surface.

### Randomize

Random variation of friction.

## Soft Body and Cloth subpanel

It is important to note that this collision panel is used to tell all simulations that this object is to participate in colliding/deflecting other objects on a shared layer (particles, soft bodies, and cloth).

Note! The object's shape deforms the cloth, so the cloth simulation must be inputted the "true" shape of that mesh object at that frame. This true shape is the basis shape as modified by shape keys or armatures. Therefore, the Collision Modifier must be after any of those. The image to the right shows the Modifiers panel for the Character mesh object (not the cloth object).

### Damping

Damping during a collision. The amount of bounce that the surfaces will have.

0.0 - No damping, soft bodies will have a maximum bounciness.

1.0 - Maximum damping, soft bodies will not bounce at all.

### Thickness Outer

Size of the outer collision zone.

Adds a padding distance to the outside of each face, to help to prevent intersections. The soft body will come to rest at this distance away from the face of the colliding object. Outside and inside is defined by the face normal.

### Inner

Size of the inner collision zone (padding distance).

Adds a padding distance to the inside of each face, to help to prevent intersections. The soft body will come to rest at this distance away from the face of the colliding object. Outside and inside is defined by the face normal.

### Friction

A coefficient for how slippery the cloth is when it collides with itself. For example, silk has a lower coefficient of friction than cotton.

### Single Sided

When enabled, cloth collisions are only performed on the normal side of the collider plane.

### Override Normals

When enabled, cloth collision impulses act in the direction of the collider normals.

# Cloth Simulation

Cloth simulation tries to simulate the look and behaviour of fabric. For example a flag in the wind. Or a shirt.

Cloth simulation requires a mesh object. It can be closed or open. Beware of the backside of faces then. And for closed meshes you better use soft bodies.

Once you add a cloth to a mesh a modifier gets created in the modifier properties tab. Here you can add other modifiers that may interact with the cloth simulation, like an SDS modifier. And order them in the proper way. It makes a difference if the SDS modifier is added before or after the cloth modifier.

And you can apply the cloth modifier, which freezes the simulation at the current frame. But the cloth settings are just accessible from the physics tab.

## Workflow

Add a cube.

Add a grid plane. Move it up and scale it a bit bigger. So that it is above the cube.

Add a collision physics to the cube. It is then set as a collider for the cloth simulation.

Add a cloth physics to the grid plane.

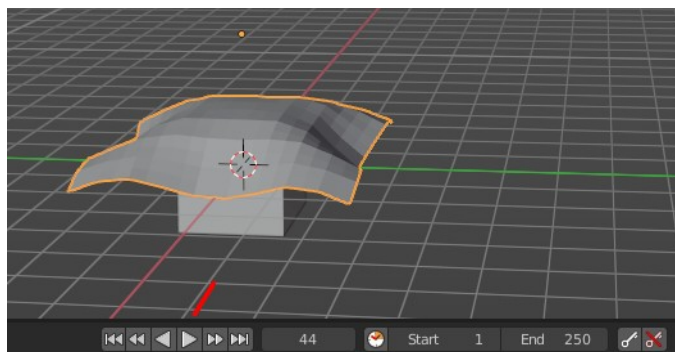

Add a subdivision surface modifier to the grid plane, and set it to simple.

Now play the simulation. Playing it creates the simulation frames. Don't jump to frames. This will skip frames for the simulation.

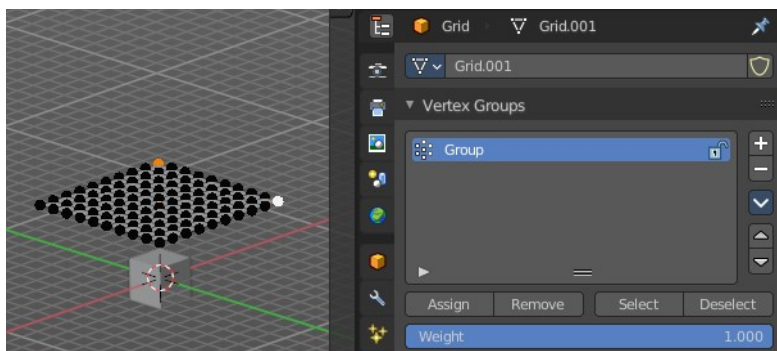

The cloth will fall down now, collide with the cube, and deform like a fabric.

Adjust the cloth settings to your needs.

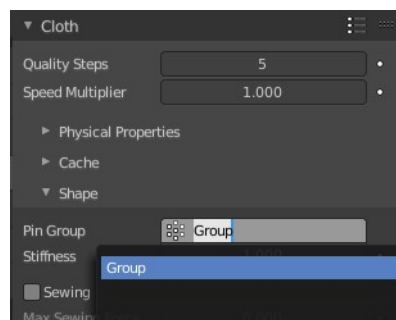

## Pinning

Enter edit mode with the grid mesh. Grab one or more vertices. Add them to a vertex group. Don't forget to press Assign ...

In the Shape subpanel, choose the vertex group into the Pin Group.

Switch to object mode. Play the animation again. You will notice that the two vertices in the vertex group are now pinned. And don't move down anymore.

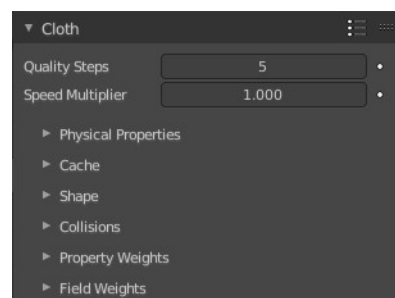

For a character you could now weight the pinned vertices to a bone. And the pinned vertices would move with the bone then.

## Note

When animating or posing the character you must begin from the bind pose. Move the character to its initial pose over several frames so the physics engine can simulate the clothing moving. Very fast movements and teleport jumps can break the physics simulation.

## Cloth Panel

## Presets

Cloth presets.

To add your own preset type in a name and click at the plus button behind the edit box. To remove a preset click at the minus button behind the preset.

## Quality Steps

Set the number of simulation steps per frame. Higher values result in better quality, but is slower.

## Speed multiplier

The cloth speed is multiplied by this value.

## Physical Properties subpanel

The physical settings for the cloth.

### Vertex Mass

The mass of the cloth material.

### Air Viscosity

Air has some thickness which slows falling things down.

### Bending Model

Some settings are just available in angular bending model. Some just in linear bending model.

## Angular

Cloth model with angular bending springs.

## Linear

Cloth model with linear bending springs (old).

## Stiffness sub subpanel

### Tension

Angular bending. How much the material resists stretching.

### Compression

Angular Bending. How much the material resists compression.

### Structural

Linear bending. Overall stiffness of the cloth.

### Shear

How much the material resists shearing.

### Bending

Wrinkle coefficient. Higher creates more large folds.

## Damping sub subpanel

### Tension

Angular bending. Amount of damping in stretching behavior.

### Compression

Angular bending. Amount of damping in compression behavior.

### Structural

Linear bending. Amount of damping in stretching behavior (only in linear bending model).

### Shear

Amount of damping in shearing behavior.

### Bending

Amount of damping in bending behavior.

## Internal Springs sub subpanel

Cloth physics are simulated through Springs connecting vertices on the surface of a mesh. But these springs only interact on the surface and only apply to 2D surfaces. 3D or Internal Springs can be used to make a mesh behave similarly to a Soft Body. Internal springs can be enabled by toggling the checkbox in the Internal Springs panel header.

You need to use the bending model Angular.

### Max Spring Creation Length

The maximum length an internal spring can have during creation. If the distance between internal points is greater than this, no internal spring will be created between these points. A length of zero means that there is no length limit.

### Max Creation Divergence

The maximum angle that is allowed to use to connect the internal points can diverge from the vertex normal.

### Check Surface Normals

Requires the points the internal springs connect to have opposite normal directions.

### Tension

How much the material resists stretching.

### Compression

How much the material resists compression.

### Vertex Group

The Tension and Compression of internal springs can be controlled via a Vertex Group to specify which the portions of the mesh have internal springs or the spring strength.

### Max Tension

Maximum tension stiffness value.

### Max Compression

Maximum Compression stiffness value.

## Pressure sub subpanel

Cloth pressure allows the simulation of soft-shelled objects such as balloons or balls that are filled with some sort of fluid. Cloth pressure can be enabled by toggling the checkbox in the Pressure panel header.

Note! Non-manifold meshes will work with cloth pressure. But pressure will escape out of the mesh holes and cause drifting or propulsion forces. One way to get around this is by using the Vertex Group to exclude the non-manifold portions of the mesh.

### Pressure

The uniform pressure that is constantly applied to the mesh. This value can be negative to simulate implosions or any other case where an object has outside pressure pushing inwards.

## Custom Volume

Use the Target Volume parameter as the initial volume for the cloth. This avoids having to use the Pressure to first inflate the object.

## Target Volume

The mesh volume where the inner/outer pressure will be the same. If set to zero the volume will not contribute to the total pressure.

## Factor

Scalar control over the overall pressure.

## Vertex Group

Cloth pressure can be controlled via a Vertex Group to specify which the portions of the mesh to apply pressure. Zero weight means no pressure while a weight of one means full pressure.

Note, faces with a vertex that has zero weight will be excluded from the Target Volume calculation.

## Cache subpanel

The cloth simulation can be cached in memory or stored on a drive. This improves real-time response and avoids unnecessary recalculation of particles. But creates also big files.

The cloth system uses a unified system for caching and baking (together with Soft Body and Emitter particle).

Important! The file needs to be saved after baking. When the file is not saved then some options are not available.

Important! The cloth settings becomes unavailable once the particle cache is baked. You need to remove the bake when you want to change the settings.

## Hints

The simulation is only calculated for positive frames in between the Start and End frames of the Cache panel, whether you bake or not. So if you want a simulation that is longer than the default frame range, you have to change the End frame.

When an animation is played, each physics system writes each frame to the cache. Note that for the cache to fill up, one has to start the playback before or on the frame that the simulation starts.

The cache is cleared automatically on changes. But not on all changes, so it may be necessary to free it manually. For example if you change a force field.

The system is protected against changes after baking. If for example the mesh changes the simulation is not calculated anew.

The bake result can be cleared by clicking on the Free Bake button in the simulation cache settings.

A simulation can only be edited in Particle Edit Mode when it has been baked in memory. And cannot be edited

if the Disk Cache is used.

If you are not allowed to write to the required sub directory caching will not happen. For example if your blend-file path is very long and your operating system has a limit on the path length that is supported.

Be careful with the sequence of modifiers in the modifier stack. You may have a different number of faces in the 3D Viewport and for rendering (For example when using subdivision surface). Then the rendered result may be very different from what you see in the 3D Viewport.

---

## Caches List

The list of available caches. The caches have no name by default. Double click to add a name.

You can store and manage multiple caches at once for the same physics object. The active cache is the one that gets used.

## Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## *Invert*

Exclude the search term instead of searching for it.

## *Sort by Name*

Sort the List by name.

## Add New Cache

Add a new cache.

## Delete current Cache

Deletes the selected cache.

## Simulation start

The start frame of the simulation.

## End

The end frame of the simulation.

## Info string

An info string. Gives different messages, dependent of the status.

## Disk Cache

Save the cache externally in a folder instead inside of the blend file. The cache of a baked simulation will be stored inside the blend-file when you save it. A folder named `blendcache_[filename]` will then be created alongside the blend-file. The blend-file must be saved first and then again.

## Use Library Path

Share the disk cache when the physics object is linked into another blend-file.

When this option is enabled, linked versions of the object will reference the same disk cache. Otherwise linked versions of the object will use independent caches.

## Compression

The compression level for cached files.

### **None**

Do not compress the cache.

### **Light**

Compression will optimize the speed of compressing/decompressing operations over file size.

### **Heavy**

Compression will result in smaller cache files, but requires more CPU power to compress / decompress.

## Bake / Delete Bake

Start baking. Once you have baked the cache the button turns into a Delete bake button. And allows you to remove the bake.

The baking progress can be seen in the footer. You need to be in Object Mode to bake.

## Calculate To Frame

Bake only up to the current frame. Limited by End frame set in the cache settings.

## Current Cache to Bake

Store any temporarily cached simulation data as a bake. Note that playing the animation will try to simulate any visible physics simulations. Depending on the physics type, this data may be temporarily cached. Normally such temporary caches are cleared when an object or setting is modified, but converting it to a bake will “save”

it.

## Bake All Dynamics

Bake all physics systems in the scene, even those of different types. Useful for baking complex setups involving interactions between different physics types.

## Delete All Bakes

Free bakes of all physics systems in the scene, even those of different types.

## Update All To Frame

Bake all physics systems in the scene to the current frame.

## Shape subpanel

### Pin Group

Vertex group to use for pinning.

The shape of the cloth can be controlled by pinning cloth to a Vertex Group. There are several ways of doing this including Weight Painting areas you want to pin. The weight of each vertex in the group controls how strongly it is pinned.

### Stiffness

Target position stiffness.

### Sewing

Another method of restraining cloth similar to pinning is sewing springs.

Sewing springs are virtual springs that pull vertices in one part of a cloth mesh toward vertices in another part of the cloth mesh. This is different from pinning which binds vertices of the cloth mesh in place or to another object. A clasp on a cloak could be created with a sewing spring. The spring could pull two corners of a cloak about a character's neck. This could result in a more realistic simulation than pinning the cloak to the character's neck since the cloak would be free to slide about the character's neck and shoulders.

Sewing springs are created by adding extra edges to a cloth mesh that are not included in any faces. They should connect vertices in the mesh that should be pulled together. For example the corners of a cloak.

### Sewing Force Max

Maximum force that can be applied by sewing springs. Zero means unbounded, but it is not recommended to leave the field at zero in most cases, as it can cause instability due to extreme forces in the initial frames where the ends of the sewing springs are far apart.

## Shrinking Factor

Factor by which to shrink the cloth, specifying a negative value controls the amount for the cloth to grow.

## Dynamic Mesh

Allows animating the rest shape of cloth using shape keys or modifiers (e.g. an Armature modifier or any deformation modifier) placed above the Cloth modifier. When it is enabled, the rest shape is recalculated every frame, allowing unpinned cloth to squash and stretch following the character with the help of shape keys or modifiers, but otherwise move freely under control of the physics simulation.

Normally cloth uses the state of the object in the first frame to compute the natural rest shape of the cloth, and keeps that constant throughout the simulation. This is reasonable for fully realistic scenes, but does not quite work for clothing on cartoon style characters that use a lot of squash and stretch.

## Collisions subpanel

In most cases, a piece of cloth collides with other objects in the environment. To ensure proper simulation, there are several items that have to be set up and working together.

- The Cloth object must be told to participate in collisions.
- Optionally (but recommended) tell the cloth to collide with itself.
- Other objects must be visible to the Cloth object via shared layers.
- The other objects must be mesh objects.
- The other objects may move or be themselves deformed by other objects (like an armature or shape key).
- The other mesh objects must be told to deflect the cloth object.
- The blend-file must be saved in a directory so that simulation results can be saved.
- You then Bake the simulation. The simulator computes the shape of the cloth for a frame range.
- You can then edit the simulation results, or make adjustments to the cloth mesh, at specific frames.
- You can make adjustments to the environment or deforming objects, and then re-run the cloth simulation from the current frame forward.

## Troubleshooting

If you encounter some problems with collision detection, there are a few ways to fix them:

The fastest solution is to increase the Distance for Object/Self Collisions. This will be the fastest way to fix the

clipping; however, it will be less accurate and will not look as good. Using this method tends to make it look like the cloth is resting on air, and gives it a very rounded look.

A second method is to increase the Quality (in the Cloth panel). This results in smaller steps for the simulator and therefore to a higher probability that fast-moving collisions get caught. You can also increase the Collisions Quality to perform more iterations to get collisions solved.

If none of the methods help, you can easily edit the cached/baked result in Edit Mode afterwards.

If the Cloth is torn by the deforming mesh; increase the stiffness settings.

## Quality

A general quality setting. Higher numbers take more time but ensure less tears and penetrations through the cloth.

## Object Collisions sub subpanel

If the cloth object needs to be deflected by some other object. To deflect a cloth, the object must be enabled as an object that collides with the cloth object. To enable objects to collide with cloth objects enable collision physics for the collider object (not on the cloth object).

Note! If your colliding object is not a mesh object, such as a NURBS surface, or a text object, you must convert it to a mesh object first.

## Distance

The distance another object must get to the cloth for the simulation to repel the cloth out of the way. Smaller values might give errors but gives some speed-up while larger will give unrealistic results if too large and can be slow. It is best to find a good in between value.

## Impulse Clamping

Prevents explosions in tight and complicated collision situations by restricting the amount of movement after a collision.

## Collision Collection

Only objects that are a part of this Collection can collide with the cloth. Note that these objects must also have Collision physics enabled.

## Self-Collisions sub subpanel

Real cloth cannot penetrate itself, so you normally want the cloth to self-collide. Enable this to tell the cloth object that it should not penetrate itself. This adds to the simulation's compute time, but provides more realistic results.

Tip! A flag, viewed from a distance does not need this enabled, but a close-up of a cape or blouse on a character should have this enabled.

## Friction

A coefficient for how slippery the cloth is when it collides with itself. For example, silk has a lower coefficient of friction than cotton.

## Distance

As cloth at this distance begins to repel away from itself. Smaller values might give errors but gives some speed-up while larger will give unrealistic results if too large and can be slow. It is best to find a good in between value.

## Impulse Clamping

Prevents explosions in tight and complicated collision situations by restricting the amount of movement after a collision.

## Vertex Group

Only vertices that are a part of this Vertex Group can collide with each other.

## Property Weights subpanel

This panel is used to constrain certain cloth properties to a certain vertex group. The properties that they control can be found in a combination of the Physical Properties and Shape panels.

## Structural Group

Defines a vertex group to control over structural stiffness.

## Max Tension

Maximum tension stiffness value.

## Max Compression

Maximum Compression stiffness value.

## Shear Group

Vertex group for fine control over shear stiffness.

## Max Shearing

Maximum shear scaling value.

## Bending Group

Vertex group for fine control over bending stiffness.

## Max Bending

Maximum bending stiffness value.

## Shrinking Group

Vertex group for shrinking cloth.

## Max Shrinking

Max amount to shrink cloth by, specifying a negative value controls the max amount for the cloth to grow.

# Field Weights subpanel

Cloth simulation is also influenced by external force effectors. This panel allows you to adjust these forces.

## Dynamic Paint

Dynamic paint is a modifier and physics system that allows to paint at the mesh surface of an object. You need an object that is set up as the canvas. And an object that is set up as the brush to create the required vertex colors, image sequences or displacement.

This combination makes many effects possible. For example footsteps in the snow, raindrops that make the ground wet, paint that sticks to walls, or objects that gradually freeze.

Creating a dynamic paint physics adds a modifier in the modifier tab. But the settings can just be adjusted from the physics tab.

### Type

The Dynamic Paint modifier has two different types Canvas and Brush. And the panel content shows either the settings for the canvas or for the brush type.

Note! You can also enable brush and canvas simultaneously by add canvas and add brush. In that case same object's "brush" does not influence its "canvas", but can still interact with other objects in the scene.

## Workflow

### Workflow Paint simulation

Create a grid object. Scale it a bit bigger. Add a SDS modifier with type simple.

Add a dynamic paint physics. And set the type to Canvas. In the surface section set the type to Waves.

Create a sphere.

Add a dynamic paint physics. And set the type to Brush.

Paint is a vertex painting effect. So in the viewport shading enable vertex color to see the paint effect.

For the canvas object go to the end of the list, remove both, the paintmap layer and the wetmap layer, and add a new paintmap layer.

The paint effect is a dynamic and so an animated effect. And so you need to play the animation. Now, with the animation playing, move the sphere into the grid object. You will see the surface of the grid object react to the contact with the sphere.

You can of course also set keyframes to record the motion of the brush sphere.

## Workflow Displace simulation

Create a grid object. Scale it a bit bigger. Add a SDS modifier with type simple.

Add a dynamic paint physics. And set the type to Canvas. In the surface section set the type to Waves.

Create a sphere.

Add a dynamic paint physics. And set the type to Brush.

The paint effect is a dynamic and so an animated effect. And so you need to play the animation. Now, with the animation playing, move the sphere into the grid object. You will see the surface of the grid object react to the contact with the sphere.

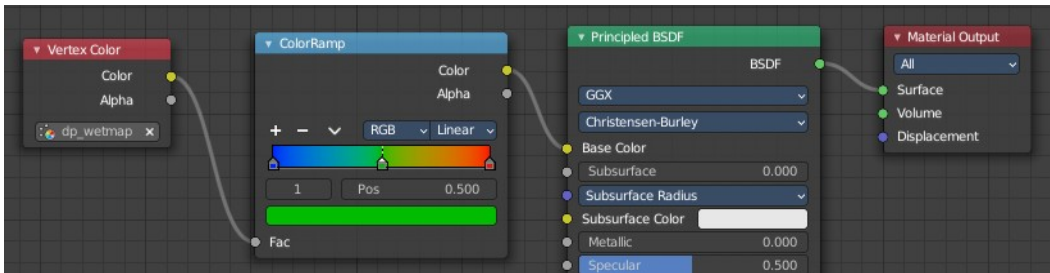

You can of course also set keyframes to record the motion of the brush sphere.

## Workflow Weight simulation

The workflow is similar to the Paint workflow. But the result cannot be visualized. The image at the right shows the in between step across paint. And you need to bake the result to use it.

Node setup to visualize the result with the Paint method. You need to be in viewport shading method Material Preview. And in the Output of the Dynamic Paint the wetmap layer needs to be activated so that it shows up in the vertex color node.

When done switch to surface type Weight.

In the Output subpanel of Dynamic Paint activate the Vertex Group. This is done by clicking at the +button behind the vertex group.

Bake the result.

The vertex group output from dynamic paint can now be used in quick smoke for example, to determine where smoke should appear.

## Workflow Ocean simulation

Create a grid object. Scale it a bit bigger. Add a SDS modifier with type simple.

Add a dynamic paint physics. And set the type to Canvas. In the surface section set the type to Waves.

Create a sphere.

Add a dynamic paint physics. And set the type to Brush.

The paint effect is a dynamic and so an animated effect. And so you need to play the animation. Now, with the animation playing, move the sphere into the grid object. You will see the surface of the grid object react to the contact with the sphere.

You can of course also set keyframes to record the motion of the brush sphere.

## Canvas - Settings subpanel

The Canvas type makes object receive paint from Dynamic Paint brushes.

### Add Canvas / Remove Canvas

Add a canvas. When a canvas is added the button turns into the remove canvas button.

### Active Point Cache Index

A list of the available point caches. You can add more than one surface here. The type of this surface can be changed in the surfaces sub tab then. But just one surface can be the active one.

Double clicking at the name allows to rename the surface point cache.

Is Active allows you to turn off the surface point cache.

## Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## Invert

Exclude the search term instead of searching for it.

## Sort by Name

Sort the List by name.

## Add Surface Slot

Adds a surface slot

## Remove Surface Slot

Removes the selected surface slot.

## Format

Each surface has a certain format and type. Format determines how data is stored and outputted.

## Vertex

Dynamic Paint operates directly on mesh vertex data. Results are stored by point cache and can be displayed in viewport. However, using vertex level also requires a highly subdivided mesh to work.

## Image Sequences

Dynamic Paint generates UV wrapped image files of defined resolution as output.

## Resolution

Image Sequence format. The output resolution of the single images.

## Anti-Aliasing

Use Anti-Aliasing to smooth paint edges. The antialiasing is using a 5× multi sampling method.

## Frame Start

The start frame of the surface processing.

## End

The end frame of the surface processing.

## Sub-steps

Sub-steps are extra samples between frames. They are usually required when there is a very fast brush.

# Canvas - Surface subpanel

## Surface Type

Each surface has a “type” that defines what surface is used for. Dependent of the chosen surface type you will see other settings.

## Paint

Paint outputs color and wetness values. In case of vertex surfaces, results are outputted as vertex colors.

A wetmap is a black-and-white output that visualizes paint wetness. White being maximum wetness, black being completely dry. It is usually used as mask for rendering. Some “paint effects” affect wet paint only.

## Brush Collection

Define a specific collection to pick brush objects from.

## Scale Influence

The influence the brush objects have on this surface.

## Radius

Adjust radius of proximity brushes or particles for this surface.

## Dissolve

Make surface changes disappear over time.

## Time

Approximately in how many frames the dissolve should happen.

## Slow

Use logarithmic dissolve. This makes high values to fade faster than low values.

## Dry

Make surface wetness dry over time. Completely disable drying can be used

for indefinitely spreading paint.

### Time

Approximately in how many frames the dry should happen.

### Color

Define the wetness level when paint colors start to shift to surface “background”. Lower values can be useful to prevent spreading paint from becoming transparent as it dries, while higher values give better results in general.

### Slow

Use logarithmic dissolve. This makes high values to fade faster than low values.

## Displace

Outputs intersection depth from brush objects. It deforms the mesh.

Tip! If the displace output seems too rough it usually helps to add a Smooth Modifier after Dynamic Paint in the modifier stack.

### Max Displace

The maximum level of intersection depth, larger values will be clamped to this value.

### Displace Factor

The multiplier for the intersection depth. You can use it to adjust final displace strength or use negative values to paint bumps.

### Incremental

A new displace is added cumulatively on top of an existing displace.

### Brush Collection

Define a specific collection to pick brush objects from.

### Scale Influence

The influence the brush objects have on this surface.

### Radius

Adjust radius of proximity brushes or particles for this surface.

### Dissolve

Make surface changes disappear over time.

## Time

Approximately in how many frames the dissolve should happen.

## Slow

Use logarithmic dissolve. This makes high values to fade faster than low values.

## Weight

This special surface type is only available for vertex format output. It outputs vertex weight groups that can be used by other Blender modifiers and tools.

Tip! It is usually preferred to use “proximity” based brushes for weight surfaces to allow smooth falloff between weight values.

It requires a material to display the result.

## Brush Collection

Define a specific collection to pick brush objects from.

## Scale Influence

The influence the brush objects have on this surface.

## Radius

Adjust radius of proximity brushes or particles for this surface.

## Dissolve

Make surface changes disappear over time.

## Time

Approximately in how many frames the dissolve should happen.

## Slow

Use logarithmic dissolve. This makes high values to fade faster than low values.

## Waves

This surface type produces simulated wave motion. Like displace, wave surface also uses brush intersection depth to define brush strength.

Tip! In some cases the wave motion gets very unstable around brush. It usually helps to reduce wave speed, brush “wave factor” or even the resolution of mesh/surface.

## Open Borders

Allows waves to pass through mesh “edges” instead of reflecting

from them.

### **Timescale**

Directly adjusts simulation speed without affecting simulation outcome. Lower values make simulation go slower and otherwise.

### **Speed**

Affects how fast waves travel on the surface. This setting is also corresponds to the size of the simulation. Half the speed equals surface double as large.

### **Damping**

Reduces the wave strength over time. Basically adjusts how fast wave disappears.

### **Spring**

Adjusts the force that pulls water back to “zero level”.

### **Smoothness**

Limit maximum steepness of wave slope between simulation points. Higher values results in smoother waves and higher calculation time.

### **Brush Collection**

Define a specific collection to pick brush objects from.

### **Scale Influence**

The influence the brush objects have on this surface.

### **Radius**

Adjust radius of proximity brushes or particles for this surface.

## Canvas - Cache subpanel

Vertex format only. For image sequence type the caching is done in the output panel.

The canvas simulation can be cached in memory or stored on a drive. This improves real-time response and avoids unnecessary recalculation of particles. But creates also big files.

The canvas system uses a unified system for caching and baking (together with Cloth, Soft Body and Emitter particle).

Important! The file needs to be saved after baking. When the file is not saved then some options are not

available.

Important! The canvas settings becomes unavailable once the particle cache is baked. You need to remove the bake when you want to change the settings.

## Hints

The simulation is only calculated for positive frames in between the Start and End frames of the Cache panel, whether you bake or not. So if you want a simulation that is longer than the default frame range, you have to change the End frame.

When an animation is played, each physics system writes each frame to the cache. Note that for the cache to fill up, one has to start the playback before or on the frame that the simulation starts.

The cache is cleared automatically on changes. But not on all changes, so it may be necessary to free it manually. For example if you change a force field.

The system is protected against changes after baking. If for example the mesh changes the simulation is not calculated anew.

The bake result can be cleared by clicking on the Free Bake button in the simulation cache settings.

A simulation can only be edited in Particle Edit Mode when it has been baked in memory. And cannot be edited if the Disk Cache is used.

If you are not allowed to write to the required sub directory caching will not happen. For example if your blend-file path is very long and your operating system has a limit on the path length that is supported.

Be careful with the sequence of modifiers in the modifier stack. You may have a different number of faces in the 3D Viewport and for rendering (For example when using subdivision surface). Then the rendered result may be very different from what you see in the 3D Viewport.

## Caches List

The list of available caches. The caches have no name by default. Double click to add a name.

You can store and manage multiple caches at once for the same physics object. The active cache is the one that gets used.

## Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## *Invert*

Exclude the search term instead of searching for it.

## Sort by Name

Sort the List by name.

## Add New Cache

Add a new cache.

## Delete current Cache

Deletes the selected cache.

## Info string

An info string. Gives different messages, dependent of the status.

## Bake / Delete Bake

Start baking. Once you have baked the cache the button turns into a Delete bake button. And allows you to remove the bake.

The baking progress can be seen in the footer. You need to be in Object Mode to bake.

## Calculate To Frame

Bake only up to the current frame. Limited by End frame set in the cache settings.

## Current Cache to Bake

Store any temporarily cached simulation data as a bake. Note that playing the animation will try to simulate any visible physics simulations. Depending on the physics type, this data may be temporarily cached. Normally such temporary caches are cleared when an object or setting is modified, but converting it to a bake will “save” it.

## Bake All Dynamics

Bake all physics systems in the scene, even those of different types. Useful for baking complex setups involving interactions between different physics types.

## Delete All Bakes

Free bakes of all physics systems in the scene, even those of different types.

## Update All To Frame

Bake all physics systems in the scene to the current frame.

## Canvas - Effects subpanel

Surface Type Paint only. It generates animated movement on canvas surface.

For spread and drip effects, only “wet paint” is affected, so as the paint dries, movement becomes slower until it stops.

### Spread

Paint slowly spreads to surrounding points eventually filling all connected areas.

### Speed

How fast the spread effect moves on the canvas surface.

### Color

How fast the colors get mixed within wet paint.

### Drip

Paint moves in specific direction specified by Blender force fields, gravity and velocity with user-defined influences.

### Velocity

How much surface velocity affect dripping.

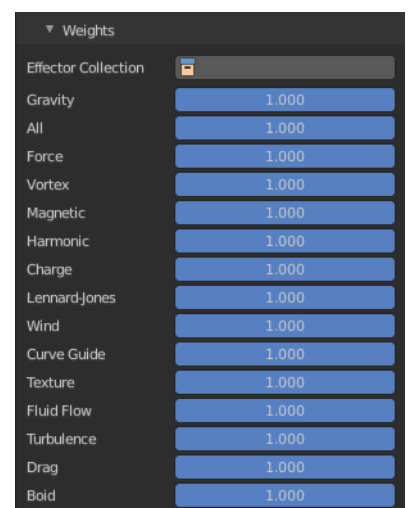

### Acceleration

How much surface acceleration affects dripping.

### Weights

The dripping is influenced by physical forces. This panel allows you to adjust the amount of the single effector forces.

Effector collection allows you to limit the forces to a collection only.

## Shrink

Painted area slowly shrinks until disappears completely.

## Speed

How fast shrink effects move on the canvas surface.

## Canvas - Initial color subpanel

Surface Type Paint only. Allows you to define the initial color of the canvas.

### None

No initial color is used.

### Color

Define an initial color.

### Color

Clicking at the color field opens a color picker where you can choose a color.

### UV Texture

Use a UV texture as an initial color.

### Texture

The texture to use. The texture that is meant here is not an image texture. But a created one. This can be done in the Texture tab.

### UV Map

The UV map of the mesh. Usually you will just have one UV map available. But a mesh can have several ones.

### Vertex Color

Set an initial vertex color. You need to have a vertex color at the mesh. Then choose it here.

To create a vertex color layer go to the Object data properties to the Vertex color panel, and add a new one. Or simply enter the vertex paint mode and paint at least one vertice with a vertex color. Then a vertex color layer gets

created.

## Canvas - Output subpanel

### With Vertex Format

#### With surface type Paint

The Paintmap Layer `dp_paintmap` and Wetmap Layer `dp_wetmap` map types are vertex colors.

Red means this map type is deactivated. To activate the layers click at the + button at the right.

Once activated they can be found in the Vertex colors panel in the Object Data tab.

#### With surface type Weight

The Vertex Group `dp_dp_weight` is a vertex group.

Red means this map type is deactivated. To activate the layers click at the + button at the right.

Once activated it can be found in the Vertex Group panel in the Object Data tab.

### With Image Sequence format

#### With surface type Paint

##### ***Bake Image Sequence***

Bake the image sequence to file.

##### ***Cache Path***

The path where the cache images are stored.

##### **Accept**

Open a file browser to choose another cache directory.

##### ***Premultiply Alpha***

Multiply color by alpha.

##### ***Paintmaps***

Use paintmaps.

### Name

The name of the paintmap to use.

### Wetmaps

Use wetmaps

### Name

The name of the wetmap to use.

## With surface type Displace

### Bake Image Sequence

Bake the image sequence to file.

### Cache Path

The path where the cache images are stored.

### Accept

Open a file browser to choose another cache directory.

### Premultiply Alpha

Multiply color by alpha.

### Filename

The name that is used to save the output from this surface.

### Displace Type

What displace type to use.

### Max Displace

Maximum level of depth intersection in object space. Use 0.0 to disable it.

## With surface type Waves

### Bake Image Sequence

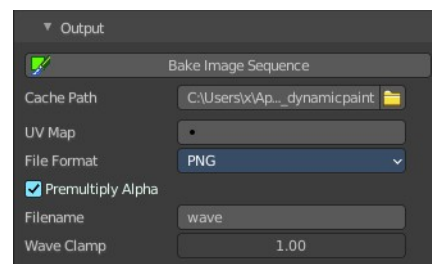

Bake the image sequence to file.

### Cache Path

The path where the cache images are stored.

### Accept

Open a file browser to choose another cache directory.

### ***UV Map***

UV map name to use. Leave empty when you don't work with UV maps.

### ***File Format***

Save the images either with Open EXR or with PNG file format.

### ***Premultiply Alpha***

Multiply color by alpha.

### ***Filename***

The name that is used to save the output from this surface.

### ***Wave Clamp***

Maximum level of depth intersection in object space. Use 0.0 to disable it.

## Soft Body

Soft body simulation is used for simulating soft deformable objects. It was designed primarily for adding secondary motion to animation, like jiggle for body parts of a moving character.

It also works for simulating more general soft objects that bend, deform and react to forces like gravity and wind, or collide with other objects.

The soft body simulation works by combining existing animation on the object with forces acting on it. There are exterior forces like gravity or force fields and interior forces that hold the vertices together. This way you can simulate the shapes that an object would take on in reality if it had volume, was filled with something, and was acted on by real forces.

Soft bodies can interact with other objects through Collision. They can interact with themselves through Self-Collision.

The result of the soft body simulation can be converted to a static object. You can also bake edit the simulation, means edit intermediate results and run the simulation from there.

Soft bodies can be used for:

- Jiggle on moving characters.
- Elastic and deformable objects made of materials like rubber or gelatin.
- Tree branches moving in the wind, swinging ropes, and the like.
- Flags, wide sleeves, cushions or other simple fabric reacting to forces.

Soft body simulation works for all objects that have vertices or control points (meshes, curves, surfaces, and lattices).

Soft body simulation is a dynamic effect. It needs an animation.

### Tips

Soft bodies work especially well if the objects have an even vertex distribution. You need enough vertices for good collisions. You change the deformation (the stiffness) if you add more vertices in a certain region.

The calculation of collisions may take a long time. If something is not visible, why calculate it?

To speed up the collision calculation it is often useful to collide with an additional, simpler, invisible, somewhat larger object.

Use soft bodies only where it makes sense. If you try to cover a body mesh with a tight piece of cloth and

animate solely with soft body, you will have no success. Self-collision of soft body hair may be activated, but that is a path that you have to wander alone. We will deal with Collisions in detail later.

Try and use a Lattice or a Curve Guide soft body instead of the object itself. This may be magnitudes faster.

## Soft Body panel

### Collision Collection

Limit the soft body simulation to objects in a collection

## Object subpanel

### Friction

The friction of the surrounding medium. Generally friction dampens a movement. The larger the friction, the more viscous is the medium. Friction always appears when a vertex moves relative to its surround medium.

### Mass

Mass value for vertices. Larger mass slows down acceleration, except for gravity where the motion is constant regardless of mass. Larger mass means larger inertia, so also braking a soft body is more difficult.

### Control Point

You can paint weights and use a specified vertex group for mass values.

## Simulation subpanel

### Speed

You can control the internal timing of the soft body system with this value. It sets the correlation between frame rate and tempo of the simulation. A free falling body should cover a distance of about ten meters after one second. You can adjust the scale of your scene and simulation with this correlation. If you render with 25 frames per second, you will have to set Speed to 1.3.

## Cache subpanel

The soft body simulation can be cached in memory or stored on a drive. This improves real-time response and avoids unnecessary recalculation of particles. But creates also big files.

The cloth system uses a unified system for caching and baking (together with cloth and Emitter particle).

Important! The file needs to be saved after baking. When the file is not saved then some options are not available.

Important! The cloth settings becomes unavailable once the particle cache is baked. You need to remove the bake when you want to change the settings.

## Hints

The simulation is only calculated for positive frames in between the Start and End frames of the Cache panel, whether you bake or not. So if you want a simulation that is longer than the default frame range, you have to change the End frame.

When an animation is played, each physics system writes each frame to the cache. Note that for the cache to fill up, one has to start the playback before or on the frame that the simulation starts.

The cache is cleared automatically on changes. But not on all changes, so it may be necessary to free it manually. For example if you change a force field.

The system is protected against changes after baking. If for example the mesh changes the simulation is not calculated anew.

The bake result can be cleared by clicking on the Free Bake button in the simulation cache settings.

A simulation can only be edited in Particle Edit Mode when it has been baked in memory. And cannot be edited if the Disk Cache is used.

If you are not allowed to write to the required sub directory caching will not happen. For example if your blend-file path is very long and your operating system has a limit on the path length that is supported.

Be careful with the sequence of modifiers in the modifier stack. You may have a different number of faces in the 3D Viewport and for rendering (For example when using subdivision surface). Then the rendered result may be very different from what you see in the 3D Viewport.

## Caches List

The list of available caches. The caches have no name by default. Double click to add a name.

You can store and manage multiple caches at once for the same physics object. The active cache is the one that

gets used.

## Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## *Invert*

Exclude the search term instead of searching for it.

## *Sort by Name*

Sort the List by name.

## Add New Cache

Add a new cache.

## Delete current Cache

Deletes the selected cache.

## Simulation start

The start frame of the simulation.

## End

The end frame of the simulation.

## Cache Step

Number of frames between cached frames.

## Info string

An info string. Gives different messages, dependent of the status.

## Disk Cache

Save the cache externally in a folder instead inside of the blend file. The cache of a baked simulation will be stored inside the blend-file when you save it. A folder named `blendcache_[filename]` will then be created alongside the blend-file. The blend-file must be saved first and then again.

## Use Library Path

Share the disk cache when the physics object is linked into another blend-file.

When this option is enabled, linked versions of the object will reference the same disk cache. Otherwise linked versions of the object will use independent caches.

## Compression

The compression level for cached files. It becomes available when Disk Cache is ticked

### **None**

Do not compress the cache.

### **Light**

Compression will optimize the speed of compressing/decompressing operations over file size.

### **Heavy**

Compression will result in smaller cache files, but requires more CPU power to compress / decompress.

## Bake / Delete Bake

Start baking. Once you have baked the cache the button turns into a Delete bake button. And allows you to remove the bake.

The baking progress can be seen in the footer. You need to be in Object Mode to bake.

## Calculate To Frame

Bake only up to the current frame. Limited by End frame set in the cache settings.

## Current Cache to Bake

Store any temporarily cached simulation data as a bake. Note that playing the animation will try to simulate any visible physics simulations. Depending on the physics type, this data may be temporarily cached. Normally such temporary caches are cleared when an object or setting is modified, but converting it to a bake will “save” it.

## Bake All Dynamics

Bake all physics systems in the scene, even those of different types. Useful for baking complex setups involving interactions between different physics types.

## Delete All Bakes

Free bakes of all physics systems in the scene, even those of different types.

## Update All To Frame

Bake all physics systems in the scene to the current frame.

## Goal subpanel

Use the motion from animations (F-curves, armatures, parents, lattices, etc.) in the simulation. The “goal” is the desired end position for vertices based on this animation.

### Vertex Group

Use a vertex group to allow per-vertex goal weights (multiplied by the Default goal).

## Goal Settings sub subpanel

### Stiffness

The spring stiffness for Goal. A low value creates very weak springs (more flexible “attachment” to the goal), a high value creates a strong spring (a stiffer “attachment” to the goal).

### Damping

The friction coefficient for Goal. Higher values give damping of the spring effect (little jiggle), and the movement will soon come to an end.

## Goal Strength sub subpanel

### Default

Goal weight/strength for all vertices when no Vertex Group is assigned. If you use a vertex group the weight of a vertex defines its goal.

### Min / Max

When you use a vertex group, you can use the Minimum and Maximum to fine-tune (clamp) the weight values. The lowest vertex weight will become Minimum, the highest value becomes Maximum.

## Edges subpanel

### Use Edges

Allow the edges in a mesh object to act like springs. See interior forces.

### Springs

Use a specified vertex group for spring strength values.

## Pull

The spring stiffness for edges (how much the edges are allowed to stretch). A low value means very weak springs (a very elastic material), a high value is a strong spring (a stiffer material) that resists being pulled apart.

A value of 0.5 is latex, 0.9 is like a sweater, 0.999 is a highly-starched napkin or leather. The soft body simulation tends to get unstable if you use a value of 0.999, so you should lower this value a bit if that happens.

## Push

How much the soft body resists being scrunched together, like a compression spring. Low values for fabric, high values for inflated objects and stiff material.

## Damp

The friction for edge springs. High values (max of 50) dampen the Push/Pull effect and calm down the cloth.

## Plastic

Permanent deformation of the object after a collision. The vertices take a new position without applying the modifier.

## Bending

This option creates virtual connections between a vertex and the vertices connected to its neighbors. This includes diagonal edges. Damping also applies to these connections.

## Length

The edges can shrink or be blown up. This value is given in percent, 0 disables this function. 100% means no change, the body keeps 100% of its size.

## Collision Edge

Checks for edges of the soft body mesh colliding.

## Face

Checks for any portion of the face of the soft body mesh colliding (computationally intensive!). While Face enabled is great, and solves lots of collision errors, there does not seem to be any dampening settings for it, so parts of the soft body object near a collision mesh tend to “jitter” as they bounce off and fall back, even when there is no motion of any meshes. Edge collision has dampening, so that can be controlled, but Deflection dampening value on a collision object does not seem to affect the face collision.

## Aerodynamics sub subpanel

Force from surrounding media. See exterior forces for details.

## Type

### **Simple**

Edges receive a drag force from the surrounding media.

### **Lift Force**

Edges receive a lift force when passing through the surrounding media.

### **Factor**

How much aerodynamic force to use. Try a value of 30 at first.

## Stiffness sub subpanel

Add diagonal springs at quad faces. This stops quad faces to collapse completely on collisions.

### **Shear**

Stiffness of the virtual springs created for quad faces.

## Self Collision subpanel

Note! Self-Collision needs Edges enabled!

Allow self collision and avoid self intersection. Every vertex is surrounded with an elastic virtual ball. Vertices may not penetrate the balls of other vertices. If you want a good result you may have to adjust the size of these balls.

## Calculation Type

### **Manual**

The Ball Size directly sets the ball size.

### **Average**

The average length of all edges attached to the vertex is calculated and then multiplied with the Ball Size setting. Works well with evenly distributed vertices.

### **Minimal / Maximal**

The ball size is as large as the smallest/largest spring length of the vertex multiplied with the Ball Size.

### **Average Min Max**

Size = ((Min + Max)/2) × Ball Size.

## Ball Size

Fraction of the length of attached edges. The edge length is computed based on the chosen algorithm. This setting is the factor that is multiplied by the spring length. It is a spherical distance (radius) within which, if another vertex of the same mesh enters, the vertex starts to deflect in order to avoid a self-collision. Set this value to the fractional distance between vertices that you want them to have their own “space”. Too high of a value will include too many vertices all the time and slow down the calculation. Too low of a level will let other vertices get too close and thus possibly intersect because there will not be enough time to slow them down.

## Stiffness

How elastic that ball of personal space is. A high stiffness means that the vertex reacts immediately to another vertex enters their space.

## Dampening

How the vertex reacts. A low value just slows down the vertex as it gets too close. A high value repulses it.

Collisions with other objects are set in the (other) Collision panel. To collide with another object they have to share at least one common layer.

## Solver subpanel

The settings in the Soft Body Solver panel determine the accuracy of the simulation.

### Step Size Min

Minimum simulation steps per frame. Increase this value, if the soft body misses fast-moving collision objects.

### Max

Maximum simulation steps per frame. Normally the number of simulation steps is set dynamically (with the Error Limit) but you have probably a good reason to change it.

### Auto-Step

Use velocities for automatic step sizes. Helps the Solver figure out how much work it needs to do based on how fast things are moving.

### Error Limit

Rules the overall quality of the solution delivered. Default 0.1. The most critical setting that defines how precise the solver should check for collisions. Start with a value that is half the average edge length. If there are visible errors, jitter, or over-exaggerated responses, decrease the value. The solver keeps track of how “bad” it

is doing and the Error Limit causes the solver to do some “adaptive step sizing”.

## Diagnostics sub subpanel

### Print Performance to Console

Prints on the console how the solver is doing.

### Estimate Matrix

Estimate matrix, split to COM, ROT, SCALE.

## Helpers sub subpanel

These settings allow you to control how Blender will react (deform) the soft body once it either gets close to or actually intersects (cuts into) another collision object on the same layer.

### Choke

Calms down (reduces the exit velocity of) a vertex or edge once it penetrates a collision mesh.

### Fuzzy

Fuzziness while on collision, high values make collision handling faster but less stable. Simulation is faster, but less accurate.

## Field Weights subpanel

Adjust how strong other forces influences the soft body simulation.

## Fluid Simulation

Fluid physics are used to simulate physical properties of liquids. Gas or smoke simulations are a subset of the fluids system.

A fluid system is made of at least two objects. The domain object defines the space in which the simulation happens. And the flow object defines the fluid simulation. There is a third object type called effector. This is a collider object for the simulation.

The smoke movement is controlled by airflow inside the domain, which can be influenced by Effector objects. Smoke will also be affected by the scene's gravity and force fields. Airflow inside the domain can affect other physics simulations via the Smoke Flow force field.

Note that you can create quick smoke and liquid effects in the Object menu in the Quick Effects sub menu. They come with the correct setup already.

## Workflow Liquid

At least a Domain object and one Flow object are required to create a fluid simulation.

First create the flow object. Add a cube. Set the flow type to Liquid.

Now create a second cube. This will be our Domain object that defines the bounds of the simulation volume. Scale it a bit bigger. You should also set the render type to wire frame. So that you can see the fluid simulation. Object properties, Viewport Display, Display as ...

In the Fluid tab set the domain type to Liquid.

Add Effector objects. Effector objects are objects at which the fluid will collide.

Assign a material to the domain object. Glass for example.

Save the blend-file.

Bake the Cache for the simulation by hitting play. There is no bake data button with the default cache settings. It happens by playing the animation.

The liquid animation may not appear immediately. You need to play the animation through for at least one time. That's how the simulation gets calculated.

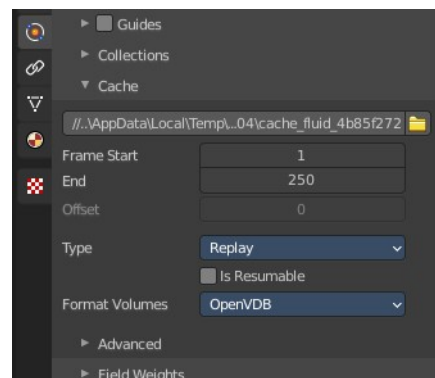

In case it does not show, let it play through a few more times until it does. It may also help to save the file and reload it. In case it still doesn't show you should check your setup.

Note, when you add effectors afterwards, then the effectors are not calculated. You need to update the cache. This can for example be done by changing cache settings for a moment. Ticking and unticking is resumable does the trick. You need to play the animation through again then.

Note! There are Quick Liquid and Quick Smoke tools which will automatically create a domain object with a basic liquid or smoke and fire material.

To render the fluid animation you need to activate Mesh in the Liquid tab. The Flip particles will not render.

You may also want to add some environment content like a hdri to have something to reflect in the water.

## Fluid Tab

### Type

Fluid simulation is made of three object types. Two are needed to get the simulation going. Domain and Flow. Effectors are additional collider objects.

## None

No fluid type defined.

## Domain

The domain object contains the entire simulation. Fluid simulations cannot leave the domain, it will either collide with the edge or disappear, depending on the domain's settings.

## Flow

Fluid Flow types are used to add or remove fluid to a domain object. Flow objects should be contained within the domain's bounding box in order to work.

## Effector

Effector objects are used as colliders and to influence the fluid flow.

## Domain - Settings subpanel

### Domain type

A fluid domain can control either liquid or gas flows. Liquid domains take all liquid flow objects that intersect with the domain into consideration. Gas domains consider all intersecting Smoke, Fire, and Smoke + Fire flow objects. It is not possible to change the domain type dynamically.

### Resolution Divisions

The fluid domain is subdivided into many "cells" called voxels which make up "pixels" of fluid. This setting controls the number of subdivisions in the domain. Higher numbers of subdivisions are one way of creating higher resolution fluids.

Since the resolution is defined in terms of "subdivisions", larger domains will need more divisions to get an equivalent resolution to a small domain. For example, a one meter cube with 64 Resolution Divisions will need 128 divisions to match a 2 meter cube. The dimension used as the base division is the longest dimension of the objects bounding box. To help visualize the voxel size, the Resolution Divisions can be previewed with a small cube shown in the 3D Viewport, to show the size of these divisions.

### Time Scale

Controls the speed of the simulation. Low values result in a "slow motion" simulation, while higher values can be used to advance the simulation faster. Which is good for generating fluids to be used in still renders.

## CFL Number

Determines the maximum velocity per grid cell and is measured in grid cells per time step. Fluid is only allowed to move up to this velocity in one time step. If this threshold is exceeded the solver will subdivide the simulation step.

In general, greater CFL (Courant–Friedrichs–Lewy) numbers will minimize the number of simulation steps and the computation time. Yet it will yield less physically accurate behavior for fast fluid flows. Smaller CFL numbers result in more simulation steps per frame, longer simulation times but more accurate behavior at high velocities (e.g. fast fluid flow colliding with obstacle).

Note! When lowering the CFL number it is recommended to increase the maximum number of time steps. Similarly, when increasing the CFL number the minimum number of time steps should be adjusted.

## Use Adaptive Time Steps

Lets the solver automatically decide when to perform multiple simulation steps per frame. It takes into account the maximum and minimum number of time steps, the current Frame Rate, and the Time Scale.

## Timesteps Maximum

Maximum number of allowed time steps per frame. If needed, the solver will divide a simulation step up to this number of sub-steps.

## Minimum

Minimum number of allowed time steps per frame. The solver will always perform at least this number of simulation steps per frame.

## Using Scene Gravity X, Y , Z

By default the fluid solver will use the global scene gravity. This behavior can be disabled in the scene settings. Disabling the global gravity will enable the fluid gravity options. And then this props becomes enabled.

## Empty Space

Gas Only! Value under which voxels are considered empty space to optimize rendering.

## Delete In Obstacle

Remover any volume of fluid that intersects with an obstacle inside the domain.

## Border Collisions subpanel

Enable collisions with the following domain sides.

## Adaptive Domain

Gas only! The domain will adaptively shrink to best fit the gas, saving computation time by leaving voxels without gas out of the simulation. Unless the Add Resolution is used, the adaptive domain will not exceed the bounds of the original domain.

## Add Resolution

Number of voxels to add around the outside of the domain.

## Margin

Amount of extra space to leave around gas, measured in voxels. With very fast-moving gas larger margins may be required to prevent the gas from being cut off by the adaptive boundary, but note this will increase the number of voxels which need to be computed.

## Threshold

Smallest amount of gas a voxel can contain before it is considered empty and the adaptive domain is allowed to cut it out of the simulation.

## Domain - Gas subpanel

Domain type Gas only!

## Buoyancy Density

Buoyant force based on smoke density.

Values above 0 will cause the smoke to rise (simulating smoke which is lighter than ambient air).

Values below 0 will cause smoke to sink (simulating smoke which is heavier than ambient air).

## Buoyancy Heat

Controls how much smoke is affected by temperature. The effect this setting has on smoke depends on the per flow object Initial Temperature:

Values above 0 will result in the smoke rising when the flow object Initial Temperature is set to a positive value, and smoke sinking when the flow object Initial Temperature is set to a negative value.

Values below 0 will result in the opposite of positive values, i.e. smoke emitted from flow objects with a positive Initial Temperature will sink, and smoke from flow objects with a negative Initial Temperature will rise.

Note that smoke from multiple flow objects with different temperatures will mix and warm up or cool down until an equilibrium is reached.

## Vorticity

Controls the amount of turbulence in the smoke. Higher values will make lots of small swirls, while lower values make smoother shapes.

## Dissolve subpanel

## Domain - Liquid subpanel

Domain type Liquid only!

## Simulation Method

Determines the particle simulation method. Currently, FLIP is the only option to choose from.

## FLIP Ratio

How much FLIP velocity to use when updating liquid particle velocities. A value of 1.0 will result in a completely FLIP based simulation. Completely FLIP based simulations produce more chaotic splashes and are preferable when simulating greater quantities of liquid. When using smaller values the behavior will be less turbulent and splashes are more subtle. This is optimal when simulating scenes where the liquid is supposed to be on a small scale.

## Particle Radius

The radius of one liquid particle in grid cells units. This value describes how much area is covered by a particle and thus determines how much area around it can be considered as liquid. A greater radius will let particles cover more area. This will result in more grids cell being tagged as liquid instead of just being empty.

Whenever the simulation appears to leak or gain volume in an undesired, non physically accurate way it is a good idea to adjust this value. That is, when liquid seems to disappear this value needs to be increased. The inverse applies when too much liquid is being produced.

## Sampling

Factor that is used when sampling particles. A higher value will sample more particles. Note that particle resampling occurs at every single simulation step.

## Randomness

New particles are sampled with some randomness attached to their position which can be controlled by this field. Higher values will sample the liquid particles more randomly in inflow regions. With a value of 0.0 all new particles will be sampled uniformly inside their corresponding grid cells.

When trying to create a laminar inflow (with little randomness) or more turbulent flows (with greater randomness) this value can be useful.

## Particles Maximum

The maximum number of liquid particles per grid cell. During a simulation the number of liquid particles in a cell can fluctuate: Particles can flow into other cells or can get deleted if they move outside the narrow band. Resampling will add new particles considering this maximum.

This value sets the upper threshold of particles per cell. It is also a good way to estimate how many particles there can be in your simulation (one needs to take grid resolution into account too). This can be useful before baking and when planning a simulation.

## Minimum

The minimum number of liquid particles per grid cell. Similarly to the maximum particle threshold, this value ensures that there are at least a certain amount of particles per cell.

## Narrow Band Width

Controls the width in grid cell units of the narrow band that liquid particles are allowed to flow in. A high value will result in a thicker band and can result in an inflow region completely filled with particles. Unless the goal of the simulation is to visualize the liquid particles it is recommended to not increase the band width significantly as more particles slow down the simulation.

In some situations increasing this value can help create volume when the simulation appears to leak. In all other cases it is best to keep the narrow band as thin as possible since the liquid surface contains most details and simulating particles inside the liquid is not an optimal use of computing resources.

## Fractional Obstacles

Enables finer resolution in fluid / obstacle regions (second order obstacles).

This option reduces the “stepping effect” that results when an obstacles lies inclined inside the domain. It also makes liquid flow more smoothly over an obstacle.

## Obstacle Distance

How far apart fluid and obstacle are.

## Threshold

How much fluid is allowed in an obstacle cell

## Diffusion subpanel

Liquid diffusion defines the physical properties of a liquid and in turn define how a liquid interacts with its environment. The main factors of diffusion are the Viscosity and Surface Tension. These properties can be adjusted to create virtual liquids that behave like water, oil, honey, or any other liquid.

Warning! The simulator is not suitable for non-fluids, such as materials that do not “flow”. Simply setting the viscosity to very large values will not result in rigid body behavior, but might cause instabilities.

## Presets

Diffusion presets. To add a preset type in a name and click at the plus button. To remove a preset click at the minus button

## Base

The base of the viscosity value.

## Exponent

The exponent of the viscosity value.

## Surface Tension

Surface tension in grid units. Higher value will produce liquids with greater surface tension.

## Particles sub tab

### Spray

Create spray particles during the secondary particle simulation. Spray particles are those that appear to fly through the air above the liquid surface when there is a bigger splash.

### Foam

Create foam particles during the secondary particle simulation. Foam particles are those that solely move on the liquid surface.

### Bubbles

Create bubble particles during the secondary particle simulation. Bubble particles are those that move below the liquid surface.

Note! Enabling a secondary particle type will also create a particle system for that type of particles. Disabling a particle type will delete this particle system including its settings.

## Combined Export

Select particle types that should go into the same particle system. This option has no effect on the outcome of the simulation. It only changes the way particle systems are allocated in the particle settings.

## Upres Factor

Factor by which to enhance the resolution of the particle simulation. The scaling factor is coupled to the Resolution Divisions (i.e. the particle simulation is this times bigger than the base simulation).

## Wave Crest Potential Maximum

Upper clamping threshold for marking fluid cells as wave crests. A higher value results in less marked cells.

## Wave Crest Potential Minimum

Lower clamping threshold for marking fluid cells as wave crests. A lower value results in more marked cells.

## Trapped Air Potential Maximum

Upper clamping threshold for marking fluid cells where air is trapped. A higher value results in less marked cells.

## Trapped Air Potential Minimum

Lower clamping threshold for marking fluid cells where air is trapped. A lower value results in more marked cells.

## Kinetic Energy Potential Maximum

Upper clamping threshold for marking fluid cells where air is trapped. A higher value results in less marked cells.

## Kinetic Energy Potential Minimum

Lower clamping threshold that indicates the fluid speed where cells start to emit particles. A lower values result in generally more particles.

## Potential Radius

Radius to compute potential for each cell. Higher values are slower but create smoother potential grids.

## Particle Update Radius

Radius to compute position update for each particle. Higher values are slower but particles move less chaotic.

## Wave Crest Particle Sampling

Maximum number of particles generated per wave crest cell per frame.

## Trapper Air Particle Sampling

Maximum number of particles generated per trapped air cell per frame.

## Particle Life Maximum

Highest possible particle lifetime.

## Particle Life Minimum

Lowest possible particle lifetime.

## Bubble Buoyancy

Amount of buoyancy force that rises bubbles. A high value results in bubble movement mainly upwards.

## Bubble Drag

Amount of drag force that moves bubbles along with the fluid. A high value results in bubble movement mainly along with the fluid.

## Particles in Boundary

### *Delete*

Delete secondary particles that are inside obstacles or left the domain.

### *Push Out*

Push secondary particles that left the domain back into the domain.

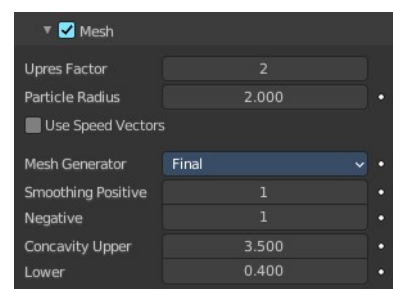

## Mesh Sub tab

Enables the display for the fluid as a mesh. When you want to render a liquid simulation then you need to convert it to a mesh object.

## Upres Factor

Factor by which to enhance the resolution of the mesh. The scaling factor is coupled to the Resolution Divisions (i.e. the mesh is this times bigger than the base simulation).

## Particle Radius

The radius of one liquid particle in grid cells units. This value describes how much area is covered by a particle and thus determines how much area around it can be considered as liquid. A greater radius will let particles cover more area. This will result in meshes covering more volume around liquid particles.

## Use Speed Vectors

Store speed vectors on drive.

## Mesh Generator

The mesh generator method determines the accuracy of the mesh.

The Final option produces a higher quality mesh and provides more configuration option.

The Preview option is faster. But not as smooth. And has no settings.

### Smoothing Positive

Positive mesh smoothing iterations. Higher values will make the mesh outline increasingly smooth. Yet higher values can prevent small details (e.g. smaller liquid drops) from getting meshed.

### Negative

Negative mesh smoothing iterations. Higher values will make the mesh outline sharper. High values will preserve details, however, the mesh outline will become more ragged. A single mesh particle will become less rounded and have more flat sides.

### Concavity Upper

Upper mesh concavity bound. High values tend to smoothen and fill out concave regions.

### Concavity Lower

Lower mesh concavity bound. High values tend to smoothen and fill out concave regions.

Using a lower concavity which is greater the upper concavity can result in distorted, non-manifold meshes.

## Domain - Guides subpanel

Fluid guides are used to apply forces onto the simulation. They are like simple external forces but also seek to preserve the physically accurate flow of the fluid. The Guides panel allows you to adjust guiding forces globally, for the entire domain. Enabling the guides hints the fluid solver to use the more accurate, but also computationally more expensive pressure solving step.

Even when there are no guiding objects baked or there is no guiding domain attached, the fluid solver will still perform the more expensive pressure guiding algorithm if guiding is enabled. It is therefore recommended to only enable Guides when there is a clear intention to use guiding in the simulation.

### Weight

The guiding weight.

### Size

This setting determines the size of the vertices that the guiding produces. A greater guiding size (also known as

the blur radius or “beta” guiding value) results in larger vertices.

## Velocity Factor

All guiding velocities are multiplied by this factor. That is, every cell of the guiding grid, which has the same size as the domain object, is multiplied by this factor.

## Velocity Source

The velocity guiding source. Guiding velocities can either come from objects that move inside the domain or from other fluid domains.

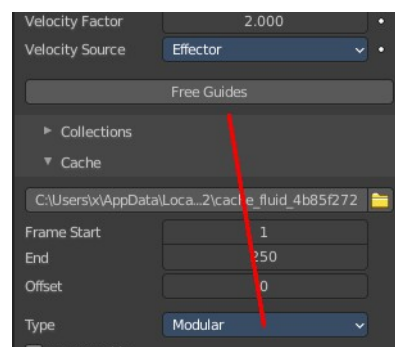

## Effector

All effector objects inside the domain will be considered for the global guiding velocity grid. Once effector objects have been baked it is not possible to change the fluid domain resolution anymore.

## Bake Guides, Free Guides

This option is only available when using the Modular cache type and when using Effector as the Velocity Source. Bake Guides writes vertex velocities of effector objects to drive. It is meant to be used before baking the fluid simulation.

The progress will be displayed in the status bar. Pressing Esc will pause the simulation.

Once the simulation has been baked, the cache can be deleted by pressing Free Guides. It is possible to pause or resume a Bake Guides process.

## Domain

When using another fluid domain as the guiding velocity source this domain may have a different resolution and may also be of a different type (e.g. the guiding domain is of type Gas while the actual domain with the guiding effect in it is of type Liquid).

In order to use a domain as the velocity source, this domain needs to be baked already.

## Guide Parent

Pick the guiding domain object when using Domain as the velocity source.

# Domain - Collections subpanel

## Flow

If set, only objects in the specified Collection will be allowed to act as Flow objects in this domain.

## Effector

If set, only objects in the specified Collection will be allowed to act as Effector objects in this domain.

## Domain - Cache subpanel

The Cache panel is used to Bake the fluid simulation and stores the outcome of a simulation so it does not need to be recalculated.

If the mesh has modifiers, the rendering settings are used for exporting the mesh to the fluid solver. Depending on the setting, calculation times and memory use might exponentially increase. For example, when using a moving mesh with Subdivision Surface as an obstacle, it might help to decrease simulation time by switching it off, or to a low subdivision level.

When the setup/rig is correct, you can always increase settings to yield a more realistic result.

Note! Fluid simulations use their own cache. All other physics simulations make use of the General Baking operators.

## Cache Directory

Directory to store baked simulation files in. Inside this directory each simulation type (i.e. mesh, particles, noise) will have its own directory containing the simulation data.

## Accept

Open a file browser to set a directory.

## Frame Start

Frame on which to start the simulation. This is the first frame that will be baked.

## End

Frame on which to stop the simulation. This is the last frame that will be baked.

Note! The simulation is only calculated for positive frames between the Start and End frames of the Cache panel. So if you want a simulation that is longer than the default frame range you have to change the End frame.

## Offset

Type Modular and All. Frame offset that is used when loading the simulation from the cache. It is not considered when baking the simulation, only when loading it.

## Type

The type of the cache determines how the cache can be baked.

## Replay

The cache will be baked as the simulation is being played in the viewport.

## Modular

The cache will be baked step by step: The bake operators for this type are spread across various panels within the domain settings (e.g. the bake tool for the mesh can be found in the Mesh panel).

## All

The cache will be baked with a single tool. All selected settings will be considered during this bake. The bake tool for this type can be found in the Cache panel.

## Is Resumable

Extra data will be saved so that you can resumed baking after pausing. Since more data will be written to drive it is recommended to avoid enabling this option when baking at high resolutions.

## Format Volumes

File format for volume based simulation data (i.e. grids and particles).

## Uni Cache

Blender's own caching format with some compression. Each simulation object is stored in its own .uni cache file.

## OpenVDB

Advanced and efficient storage format. All simulation objects (i.e. grids and particles) are stored in a single .vdb file per frame.

## Meshes

With Mesh activated.

File format for the mesh cache files.

## Binary Object

Mesh data files with some compression.

## Object

Simple, standard data format for mesh data.

## Bake All, Free All

This option is only available when using the All cache type. Bake All will run the simulation considering all parameters from the settings.

The progress will be displayed in the status bar. Pressing Esc will abort the

simulation.

Once the simulation has been baked, the cache can be deleted by pressing Free All. It is not possible to pause or resume a Bake All process as only the most essential cache files are stored on drive.

## Advanced

Shows with Format Volumes OpenVDB.

## Compression Volumes

Compression format that is used when writing OpenVDB cache files.

### None

Cache files will be written without any compression.

### Zip

Cache files will be written with Zip compression. Effective but slower than Blosc.

### Blosc

Cache files will be written with Blosc compression. Multi-threaded compression, similar in size and quality to Zip compression.

## Precision Volumes

Precision level that is used when writing OpenVDB cache files.

### Float (Full)

Volumetric data (e.g. grid values, particle positions) will be written with full precision (32 bit).

### Float (Half)

Volumetric data (e.g. grid values, particle positions) will be written with half precision (16 bit).

## Export Mantaflow Script

### Hidden debug feature!

Export the simulation as a standalone Mantaflow script when baking the scene (exported on « Bake Data »). Usually, only developers and advanced users who know how to use the Mantaflow GUI will make use of this functionality. Use a Debug Value of 3001 to enable. The debug menu can be found in the Text editor in the File menu.

## Domain - Field Weights subpanel

This panel allows you to adjust the single forces that affects the fluid simulation.

## Domain - Viewport Display subpanel

How to display the domain in the viewport.

### Thickness

Thickness of smoke drawing in the viewport.

### Interpolation

The interpolation method to use for smoke or fire volumes in solid mode.

### Slice per Voxel

How many slices per voxel should be generated. This prop is just active with domain type gas and Slice off.

### Slice subpanel

Use manual slicing. Slice per Voxel will deactivate.

### Axis

What axis to use. Auto uses the viewport orientation. The orientation will change when you rotate the view. X Y and Z uses the world axis.

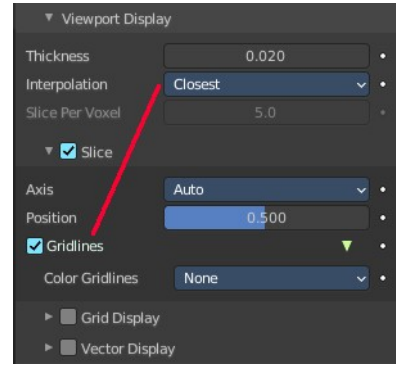

### Position

The position of the slice.

## Gridlines

Displays a grid inside the domain. This feature requires the Interpolation to be at Closest. It is inactive with the other two methods.

Activating grid lines reveals further content where you can tweak this grid further.

## Color Gridlines

The simulation field to color map onto grid lines.

None and Flags have no further settings. The following settings belong to Highlight Range. You need to have Grid Display ticked to get the settings for Highlight Range.

### Lower Bound

The lower bound of the highlight range.

### Upper Bound

The upper bound of the highlight range.

### Color

The color to highlight the range

### Cell Type

The cell type to be highlighted.

## Grid display subpanel

Render a simulation field while mapping its voxel values to the color of a ramp or using a predefined color code.

## Domain type Liquid

### Field

Choose the levelset representation of the fluid.

### Scale

The multiplier to scale the selected field to color map.

## Domain type Gas

### Field

Choose the levelset representation of the fluid.

### Scale

The multiplier to scale the selected field to color map.

### Color ramp

Define the colors of the color ramp.

### Controls

+

Add a stop to your color ramp. The stop will be added after the selected one, in the middle to the next one.

-

Deletes the selected color stop from the list.

### Tools menu

#### Flip Color Ramp

Flips the gradient, inverting the values of the color ramp.

### **Distribute Stops from Left**

Rearrange the stops so that every step has the same space to the right.

### **Distribute Stops Evenly**

Space between all neighboring stops becomes equal.

### **Eyedropper (pipette icon) E**

An Eyedropper to sample a color or gradient from the interface to be used in the color ramp.

### **Reset Color Ramp**

Resets the color ramp to its default state.

### **Color Mode**

#### **RGB**

Blends color by mixing each color channel and combining.

#### **HSV/HSL**

Blends colors by first converting to HSV or HSL, mixing, then combining again. This has the advantage of maintaining saturation between different hues, where RGB would de-saturate, this allows for a richer gradient.

### **Interpolation**

#### **Ease**

Uses an Ease Interpolation for the color stops.

#### **Cardinal**

Uses a Cardinal Interpolation for the color stops.

#### **Linear**

Uses a Linear Interpolation for the color stops.

#### **B-Spline**

Uses a B-Spline Interpolation for the color stops.

#### **Constant**

Uses a Constant Interpolation for the color stops.

### **Color Ramp**

The color band. A click at one of the color stops makes it the active one. You can move the color stops by clicking at them and dragging them around.

### **Active Color Stop elements**

Adjust the active color stop.

### **Choose active color stop**

Choose the color stop by index.

### **Pos**

The position of the active color stop. The range goes from 0.000 to 1.000

## Vector display subpanel

### Display as

Display the vectors as Needles, Streamlines or MAC Grid.

### Magnitude

Needles and Streamlines. Scale the vectors with their magnitudes.

### MAC Grid X Y Z

Show the x y or z component of the grid.

### Field

The vector field to be represented by the display vectors

### Scale

The multiplier for scaling the vectors.

## Advanced subpanel

This panel is connected to the Gridlines in the Slice panel. It just shows when Gridlines is activated. And it is just active when Slice is activated.

### Color Gridlines

The simulation field to color map onto grid lines.

None and Flags have no further settings. The following settings belongs to Highlight Range.

### Lower Bound

The lower bound of the highlight range.

### Upper Bound

The upper bound of the highlight range.

### Color

The color to highlight the range

## Cell Type

The cell type to be highlighted.

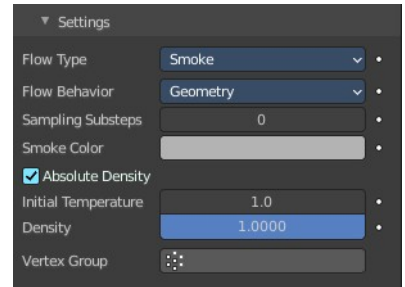

## Flow - Settings subpanel

### Flow Type

The type of the fluid in the simulation.

Fluid Flow types are used to add or remove fluid to a domain object. Flow objects should be contained within the domain's bounding box in order to work.

## Flow - Settings subpanel - Flow Type Smoke

Emit only smoke.

### Flow Behavior

Controls if the Flow object either adds (Inflow), removes (Outflow), or turns the mesh itself into fluid (Geometry).

### Inflow

This object will emit fluid into the simulation, like a water tap or base of a fire.

### Use Flow

Enables or disables the flow of fluid, this property is useful for animations to selectively enable and disable when fluid is being added to or removed from the domain.

## ***Sampling Substeps***

Number of sub-steps used to reduce gaps in emission of fluid from fast-moving sources.

## ***Smoke Color***

The color of emitted smoke. When smoke of different colors are mixed they will blend together, eventually settling into a new combined color.

## ***Absolute Density***

If this checkbox is enabled, the emitter will only produce more smoke or fire if there is space for it in the emitter region. Otherwise smoke or fire will always be produced and add up.

## ***Initial Temperature***

Difference between the temperature of emitted smoke and the domain's ambient temperature. This setting's effect on smoke depends on the domain's Heat Buoyancy.

## ***Density***

Amount of smoke to emit at once. Larger values result in more density being produced.

## ***Vertex Group***

When set, use the specified Vertex Group to control where smoke is emitted.

---

## **Outflow**

Any fluid that enters the bounding box of this object will be removed from the domain (think of a drain or a black hole). This can be useful in combination with an inflow to prevent the whole domain from filling up. Outflow objects can be animated and the area where the fluid disappears will follow the object as it moves around.

## ***Use Flow***

Enables or disables the flow of fluid, this property is useful for animations to selectively enable and disable when fluid is being added to or removed from the domain.

## ***Sampling Substeps***

Number of sub-steps used to reduce gaps in emission of fluid from fast-moving sources.

---

## **Geometry**

All regions of this object that are inside the domain bounding box will be used as actual fluid in the simulation. You can place more than one fluid object inside the domain. Also make sure that the surface normals are pointing outwards or else they will not simulate properly. In contrast to domain objects, the actual mesh geometry is used for fluid objects.

## Sampling Substeps

Number of sub-steps used to reduce gaps in emission of fluid from fast-moving sources.

## Smoke Color

The color of emitted smoke. When smoke of different colors are mixed they will blend together, eventually settling into a new combined color.

## Absolute Density

If this checkbox is enabled, the emitter will only produce more smoke or fire if there is space for it in the emitter region. Otherwise smoke or fire will always be produced and add up.

## Initial Temperature

Difference between the temperature of emitted smoke and the domain's ambient temperature. This setting's effect on smoke depends on the domain's Heat Buoyancy.

## Density

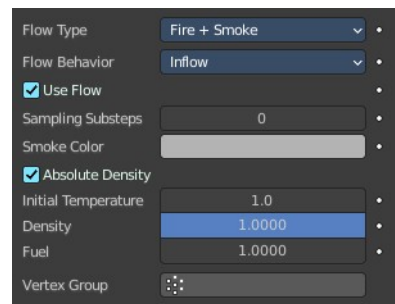

Amount of smoke to emit at once. Larger values result in more density being produced.

## Vertex Group

When set, use the specified Vertex Group to control where smoke is emitted.

# Flow - Settings subpanel - Flow Type Fire and Smoke

Emit fire and smoke.

## Flow Behavior

Controls if the Flow object either adds (Inflow), removes (Outflow), or turns the mesh itself into fluid (Geometry).

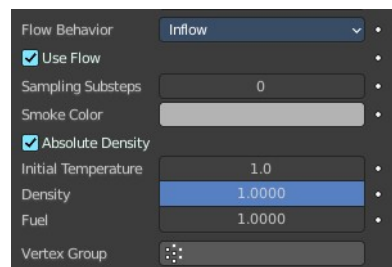

## Inflow

This object will emit fluid into the simulation, like a water tap or base of a fire.

## Use Flow

Enables or disables the flow of fluid, this property is useful for animations to

selectively enable and disable when fluid is being added to or removed from the domain.

### ***Sampling Substeps***

Number of sub-steps used to reduce gaps in emission of fluid from fast-moving sources.

### ***Smoke Color***

The color of emitted smoke. When smoke of different colors are mixed they will blend together, eventually settling into a new combined color.

### ***Absolute Density***

If this checkbox is enabled, the emitter will only produce more smoke or fire if there is space for it in the emitter region. Otherwise smoke or fire will always be produced and add up.

### ***Initial Temperature***

Difference between the temperature of emitted smoke and the domain's ambient temperature. This setting's effect on smoke depends on the domain's Heat Buoyancy.

### ***Density***

Amount of smoke to emit at once. Larger values result in more density being produced.

### ***Fuel***

Amount of "fuel" being burned per second. Larger values result in larger flames, smaller values result in smaller flames.

### ***Vertex Group***

When set, use the specified Vertex Group to control where smoke is emitted.

---

## **Outflow**

Any fluid that enters the bounding box of this object will be removed from the domain (think of a drain or a black hole). This can be useful in

combination with an inflow to prevent the whole domain from filling up. Outflow objects can be animated and the area where the fluid disappears will follow the object as it moves around.

### ***Use Flow***

Enables or disables the flow of fluid, this property is useful for animations to selectively enable and disable when fluid is being added to or removed from the domain.

### ***Sampling Substeps***

Number of sub-steps used to reduce gaps in emission of fluid from fast-moving sources.

---

## Geometry

All regions of this object that are inside the domain bounding box will be used as actual fluid in the simulation. You can place more than one fluid object inside the domain. Also make sure that the surface normals are pointing outwards or else they will not simulate properly. In contrast to domain objects, the actual mesh geometry is used for fluid objects.

## Sampling Substeps

Number of sub-steps used to reduce gaps in emission of fluid from fast-moving sources.

## Smoke Color

The color of emitted smoke. When smoke of different colors are mixed they will blend together, eventually settling into a new combined color.

## Absolute Density

If this checkbox is enabled, the emitter will only produce more smoke or fire if there is space for it in the emitter region. Otherwise smoke or fire will always be produced and add up.

## Initial Temperature

Difference between the temperature of emitted smoke and the domain's ambient temperature. This setting's effect on smoke depends on the domain's Heat Buoyancy.

## Density

Amount of smoke to emit at once. Larger values result in more density being produced.

## Fuel

Amount of "fuel" being burned per second. Larger values result in larger flames, smaller values result in smaller flames.

## Vertex Group

When set, use the specified Vertex Group to control where smoke is emitted.

# Flow - Settings subpanel - Flow Type Fire

Emit only fire. Note that the domain will automatically create some smoke to simulate smoke left by burnt fuel.

## Flow Behavior

Controls if the Flow object either adds (Inflow), removes (Outflow), or turns the mesh itself into fluid (Geometry).

## Inflow

This object will emit fluid into the simulation, like a water tap or base of a fire.

### Use Flow

Enables or disables the flow of fluid, this property is useful for animations to selectively enable and disable when fluid is being added to or removed from the domain.

### Sampling Substeps

Number of sub-steps used to reduce gaps in emission of fluid from fast-moving sources.

### Smoke Color

The color of emitted smoke. When smoke of different colors are mixed they will blend together, eventually settling into a new combined color.

### Absolute Density

If this checkbox is enabled, the emitter will only produce more smoke or fire if there is space for it in the emitter region. Otherwise smoke or fire will always be produced and add up.

### Initial Temperature

Difference between the temperature of emitted smoke and the domain's ambient temperature. This setting's effect on smoke depends on the domain's Heat Buoyancy.

### Density

Amount of smoke to emit at once. Larger values result in more density being produced.

### Fuel

Amount of "fuel" being burned per second. Larger values result in larger flames, smaller values result in smaller flames.

### Vertex Group

When set, use the specified Vertex Group to control where smoke is emitted.

## Outflow

Any fluid that enters the bounding box of this object will be removed from the domain (think of a drain or a black hole). This can be useful in combination with an inflow to prevent the whole domain from filling up. Outflow objects can be animated and the area where the fluid disappears will follow the object as it moves around.

## **Use Flow**

Enables or disables the flow of fluid, this property is useful for animations to selectively enable and disable when fluid is being added to or removed from the domain.

## **Sampling Substeps**

Number of sub-steps used to reduce gaps in emission of fluid from fast-moving sources.

## **Geometry**

All regions of this object that are inside the domain bounding box will be used as actual fluid in the simulation. You can place more than one fluid object inside the domain. Also make sure that the surface normals are pointing outwards or else they will not simulate properly. In contrast to domain objects, the actual mesh geometry is used for fluid objects.

## **Sampling Substeps**

Number of sub-steps used to reduce gaps in emission of fluid from fast-moving sources.

## **Smoke Color**

The color of emitted smoke. When smoke of different colors are mixed they will blend together, eventually settling into a new combined color.

## **Absolute Density**

If this checkbox is enabled, the emitter will only produce more smoke or fire if there is space for it in the emitter region. Otherwise smoke or fire will always be produced and add up.

## **Initial Temperature**

Difference between the temperature of emitted smoke and the domain's ambient temperature. This setting's effect on smoke depends on the domain's Heat Buoyancy.

## **Density**

Amount of smoke to emit at once. Larger values result in more density being produced.

## **Fuel**

Amount of "fuel" being burned per second. Larger values result in larger flames, smaller values result in smaller flames.

## **Vertex Group**

When set, use the specified Vertex Group to control where smoke is emitted.

Emit liquid.

## Flow Behavior

Controls if the Flow object either adds (Inflow), removes (Outflow), or turns the mesh itself into fluid (Geometry).

### Inflow

This object will emit fluid into the simulation, like a water tap or base of a fire.

#### Use Flow

Enables or disables the flow of fluid, this property is useful for animations to selectively enable and disable when fluid is being added to or removed from the domain.

#### Sampling Substeps

Number of sub-steps used to reduce gaps in emission of fluid from fast-moving sources.

### Outflow

Any fluid that enters the bounding box of this object will be removed from the domain (think of a drain or a black hole). This can be useful in combination with an inflow to prevent the whole domain from filling up.

Outflow objects can be animated and the area where the fluid disappears will follow the object as it moves around.

#### Use Flow

Enables or disables the flow of fluid, this property is useful for animations to selectively enable and disable when fluid is being added to or removed from the domain.

#### Sampling Substeps

Number of sub-steps used to reduce gaps in emission of fluid from fast-moving sources.

### Geometry

All regions of this object that are inside the domain bounding box will be used as actual fluid in the simulation. You can place more than one fluid object inside the domain. Also make sure that the surface normals are pointing outwards or else they will not simulate properly. In contrast to domain objects, the actual mesh geometry is used for fluid objects.

## Sampling Substeps

Number of sub-steps used to reduce gaps in emission of fluid from fast-moving sources.

## Flow - Settings subpanel - Flow Source

This setting defines the method used to emit fluid.

## Flow Source

How fluid is emitted. By a mesh or a particle system. Flow Type Fluid does just show the option mesh.

## Mesh

Emit fluid directly from the object's mesh.

## Is Planar

Defines the effector as either a single dimension object i.e. a plane or the mesh is non-manifold. This ensures that the fluid simulator will give the most accurate results for these types of meshes.

## Surface Emission

Maximum distance in voxels from the surface of the mesh in which fluid is emitted. Since this setting uses voxels to determine the distance, results will vary depending on the domain's resolution.

## Volume Emission

Fire or Smoke Only. Amount of fluid to emit inside the emitter mesh, where 0 is none and 1 is the full amount. Note that emitting fluid based on volume can have unpredictable results if your mesh is non-manifold.

## Particle System

Not for Flow Type Fluid. Create smoke or fire from a particle system on the flow object. which can be select with a Data ID.

Note that only Emitter type particle systems can add smoke. See Particles for information on how to create a particle system.

## Particle System

Pick the particle system to use. It must be at the same mesh.

## Set Size

Define the maximum distance in voxels at which particles can emit smoke, similar to the Surface Emission setting for mesh sources.

When disabled, particles will fill the nearest voxel with smoke.

## Size

Particle size in simulation cells.

## Flow - Settings subpanel - Initial Velocity

Note that with Flow Source Type Particles just the Source slider is showing.

### Source

Factor for the inherited velocity. A value of 1 will emit fluid moving at the same speed as the source.

### Normal

This option controls how much velocity fluid is given along a face normal. Note that, initial velocities will always be applied along all face normals. Thus with a closed flow source mesh, fluid will always be emitted in more than one direction. To set initial velocities along only one direction all normals need to point in the same direction. This is can be achieved when using a plane as the flow object.

### Initial X, Y, Z

Initial velocity along X, Y, Z coordinates in world space. This can be used in addition to the initial velocity along the Normal.

## Flow - Settings subpanel - Texture

Use a specified texture and settings to control where on the mesh smoke or fire can be emitted from. These settings have no effect on Outflow Flow Behavior.

### Texture

Choose the Texture. It must be created in the textures tab first.

### Mapping

Controls whether to use Generated UV's or manual UV mapping.

## Generated

Generated UV coordinates centered to flow object.

## Size

Overall texture scale.

## UV

Use an UV map of the flow object.

## UV Map

Choose the UV map.

## Offset

Translates the texture along the Z axis.

# Effector - Settings Subpanel

Effector objects are used to deflect fluids and influence the fluid flow. They can act as colliders or guides.

## Effector Type

### Collision

Objects of this type will collide with fluid.

### Guide

The velocity of objects of this type will be used when baking the guiding. So fluid guiding objects should move and have some velocity.

## Sampling Substeps

Number of substeps used to reduce gaps in collision of fluid from fast-moving effectors.

## Surface Thickness

Additional area around the effector that will be considered as an effector.

## Use Effector

Enables or disables the effector object effect on the fluid, this property is useful for animations to selectively enable and disable when the effector affects the fluid.

## Is Planar

Defines the effector as either a single dimension object i.e. a plane or the mesh is non-manifold. This ensures that the fluid simulator will give the most accurate results for these types of meshes.

A manifold mesh can also be declared as planar. The fluid solver will then ignore the volume inside the mesh and just emit fluid from the mesh sides.

## Velocity Factor

Effector type Guide only. Multiply the guiding object velocities by this factor. This is useful when working with multiple guiding objects and some of them should have higher or smaller velocities.

## Guide Mode

Effector type Guide only. The mode describes how guiding velocities should be written into the global guiding velocity field of the domain.

### **Maximize**

The guiding object will compare the existing velocity in the global velocity field with its own velocity. If its absolute value is greater than the absolute value in the velocity field the guiding velocity will be kept.

### **Minimize**

A guiding object will compare the existing velocity in the global velocity field with its own velocity. If its absolute value is smaller than the absolute value in the velocity field the guiding velocity will be kept.

### **Override**

The most intuitive option. A guiding object will always write its own current velocity into the global guiding velocity field. Values in the velocity field from a previous frame or guiding object will be overridden.

### **Averaged**

A guiding object will write the average of its own current velocity and the existing guiding velocity at that cell into the global guiding velocity field.

## Rigid Body

The rigid body simulation can be used to simulate the motion of solid objects. It affects the position and orientation of objects and does not deform them.

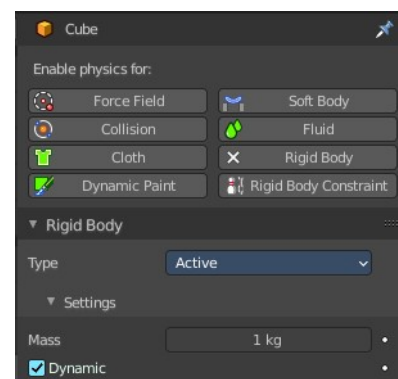

Unlike the other simulations, the rigid body sim works closer with the animation system. This means that rigid bodies can be used like regular objects and be part of parent-child relationships, animation constraints and drivers.

Rigid body physics requires a mesh object.

There are two types of rigid body: active and passive. Both types can be driven by the animation system.

Active bodies are dynamically simulated, while passive bodies remain static. It is in this regards similar to the collision physics.

The scale of the rigid body object also influences the simulation, but is always controlled by the animation system.

## Tips

As with all physics-enabled objects, pay close attention to the Animated check box in the Rigid Body panel of the Physics context in the Properties window. A common mistake is to use keyframe animation on a Passive physics object without checking the Animated box. The object will move, but the physics engine will behave as if the Passive is still in its starting place, leading to disappointment.

## Animation

The most common trick is to keyframe animate the location or rotation of an Active physics object as well as the Animated checkbox. When the curve on the Animated property switches to disabled, the physics engine takes over using the object's last known location, rotation and velocities.

Animating the strengths of various other parameters (a Motor's Target Velocity, a Hinge's limits, etc) can be used to accomplish a wide variety of interesting results.

Enabling a constraint during the physics simulation often has dramatic results as the physics engine tries to bring into alignment two objects which are often dramatically out of alignment. It is very common for the affected objects to build up enough kinetic energy to bounce themselves out of camera (and into orbit, although the physics engine is not yet capable of simulating a planet's gravity well, so scratch that).

Rigid Body dynamics can be baking to normal keyframes with Bake To Keyframes button in the Physics tab of the Tool Shelf.

## Simulation Stability

The simplest way of improving simulation stability is to increase the steps per second. However, care has to be taken since making too many steps can cause problems and make the simulation even less stable (if you need more than 1000 steps, you should look at other ways to improve stability).

Increasing the number of solver iterations helps making constraints stronger and also improves object stacking stability.

It's best to avoid small objects, as they're currently unstable. Ideally, objects should be at least 20 cm in diameter. If it's still necessary, setting the collision margin to 0, while generally not recommended, can help making small object behave more naturally.

When objects are small and/or move very fast, they can pass through each other. Besides what's mentioned above it's also good to avoid using mesh shapes in this case. Mesh shapes consist of individual triangles and therefore don't really have any thickness, so objects can pass through more easily. You can give them some thickness by increasing the collision margin.

## Combining Rigid Bodies with Other Simulations

Since the rigid body simulation is part of the animation system, it can influence other simulations just like the animation system can.

In order for this to work, the rigid body object needs to have a collision modifier. Simply click on Collision in the Physics context.

## Scaling Rigid Bodies

Rigid body objects can be scaled, also during the simulation. This work well in most cases, but can sometimes cause problems.

If dynamic scaling is not needed, rigid body objects should have the scale applied by using the Apply Scale command

## Rigid Body Panel

### Type

Role of the rigid body in the simulation. Active objects can be simulated dynamically, passive object remain static.

### Active

Object is directly controlled by simulation results. The possibility to select this type also available with Add Active button in the Physics tab of the Tool Shelf.

## Passive

Object is directly controlled by animation system. Thus, this type is not available for Rigid Body Dynamics. The possibility to select this type also available with Add Passive button in the Physics tab of the Tool Shelf.

## Settings subpanel

### Type Active

### Type Passive

The passive type does not have a mass or dynamic checkbox.

## Mass

Specifies how heavy the object is and “weights” irrespective of gravity. There are predefined mass preset available with the Calculate Mass button in the Physics tab of the Toolbar.

## Dynamic

Enables/disables rigid body simulation for object.

## Animated

Allows the rigid body additionally to be controlled by the animation system.

## Collisions subpanel

Settings around the collision behavior.

## Shape

The shape of the collider mesh.

### Box, Sphere, Capsule, Cylinder, Cone

Use this primitive shapes as a collider.

## Convex Hull

Creates a convex hull around the rigid body mesh. Concave gaps gets closed.

### Source

What shape to use for the calculation of the convex hull.

### Base

The base mesh of the object.

### Deform

Includes any deformations added to the mesh (shape keys, deform modifiers). Mesh shapes can deform during simulation.

### Final

Includes all deformations and modifiers.

## Mesh

Uses the mesh of the rigid body for collision calculation.

### Source

What shape to use for the calculation of the convex hull.

### Base

The base mesh of the object.

### Deform

Includes any deformations added to the mesh (shape keys, deform modifiers). Mesh shapes can deform during simulation.

### Final

Includes all deformations and modifiers.

## Deforming

Mesh shapes can deform during simulation.

## Compound Parent

Combines all rigid bodies of child objects into one rigid body.

You need to have at least one child object with a rigid body attached.

## Surface Response subpanel

### Friction

Resistance of object to movement. Specifies how much velocity is lost when

objects collide with each other.

## Bounciness

Tendency of object to bounce after colliding with another (0 to 1) (rigid to perfectly elastic). Specifies how much objects can bounce after collisions.

## Sensitivity subpanel

### Collision Margin

Use custom collision margining.

The collision margin is used to improve the performance and stability of rigid bodies. Depending on the shape, it behaves differently: some shapes embed it, while others have a visible gap around them.

The margin is embedded for the following shapes. Sphere, Box, Capsule, Cylinder. The margin is not embedded for the Cone and mesh object.

Convex Hull only allows for uniform scale when embedded.

### Margin

Threshold of distance near surface where collisions are still considered (best results when non-zero).

## Collections subpanel

Allows rigid body collisions allocate on different groups (maximum 20). Just the rigid bodies at the same group will collide with each other.

Holding down shift allows to add the rigid body to more than one group.

## Dynamics subpanel

Rigid body type Active only. Dynamics is used to control the physics of the rigid body simulation.

### Damping Translation

Amount of linear velocity that is lost over time.

### Rotation

Amount of angular velocity that is lost over time.

## Deactivation subpanel

Allows resting rigid bodies to become deactivated.

### Start Deactivated

Starts objects deactivated. They are activated on collision with other objects.

### Velocity Linear

Specifies the linear deactivation velocity below which the rigid body is deactivated and simulation stops simulating object.

### Angular

Specifies the angular deactivation velocity below which the rigid body is deactivated and simulation stops simulating object.

## Rigid Body Constraints

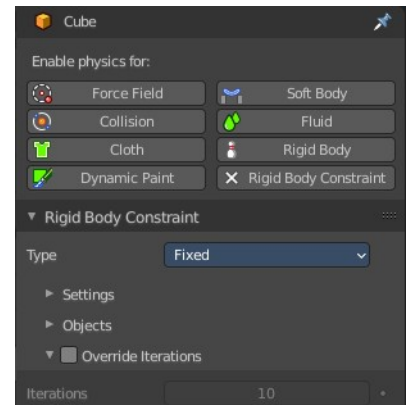

Rigid body constraints connects two rigid bodies with each other. A use case is for example to animate a chain.

Note! You need a rigid body world in the scene. This is usually created automatically in the moment when you add a rigid body.

But when you create a primitive and try to add a rigid body constraint in a new scene then you will get a warning about the missing rigid body world.

Create a rigid body first before you create a rigid body constraint.

## Workflow

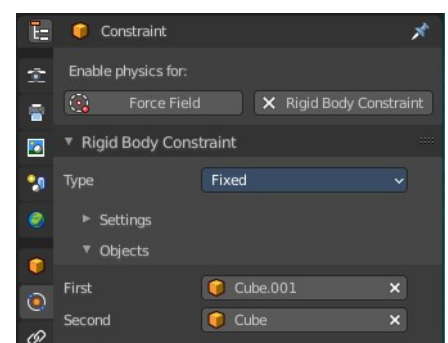

Create two objects with active rigid bodies.

Create a plane with a passive rigid body. This will be our ground.

Play the animation. The cubes will fall down independent from each other.

Now create an Empty.

You can also use one of the cubes to add the constraint. Then this cube becomes the center of the constraint.

Add a Rigid body constraint to it. And add both objects in the Object subpanel. The order does not matter in this example.

When you play the animation, then the objects will not fall independent anymore. But as one object.

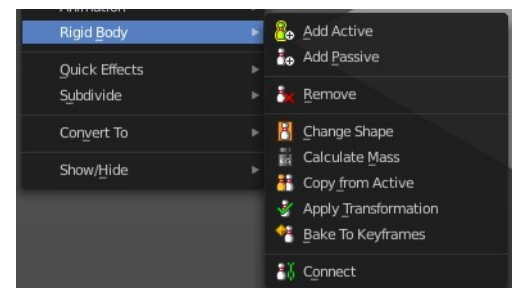

Play around with the different constraint types.

## Connect rigid bodies

The normal way goes across the Objects sub tab in the Constraint panel by adding the two objects that you want to connect. But there is a quick way to connect two rigid bodies with a constraint in the 3D view in the Object menu.

Select the first rigid body object, hold down shift, select the second rigid body object. So that both are selected. In the Object menu choose the Rigid Body menu, and here Connect at the end of the menu.

## Tips

As with all physics-enabled objects, pay close attention to the Animated checkbox in the Rigid Body panel of the Physics tab in the Properties editor. A common mistake is to use keyframe animation on a Passive physics object without checking the Animated box. The object will move, but the physics engine will behave as if the Passive is still in its starting place, leading to disappointment.

## Animation

The most common trick is to keyframe animate the location or rotation of an Active physics object as well as the Animated checkbox. When the curve on the Animated property switches to disabled, the physics engine takes over using the object's last known location, rotation and velocities.

Animating the strengths of various other parameters (a Motor's Target Velocity, a Hinge's limits, etc.) can be used to accomplish a wide variety of interesting results.

Enabling a constraint during the physics simulation often has dramatic results as the physics engine tries to bring into alignment two objects which are often dramatically out of alignment. It is very common for the affected objects to build up enough kinetic energy to bounce themselves out of camera (and into orbit, although the physics engine is not yet capable of simulating a planet's gravity well, so scratch that).

Rigid body dynamics can be baking to normal keyframes with Bake To Keyframes button in the Physics tab of

the Toolbar.

## Simulation Stability

The simplest way of improving simulation stability is to increase the steps per second. However, care has to be taken since making too many steps can cause problems and make the simulation even less stable (if you need more than 1000 steps, you should look at other ways to improve stability).

Increasing the number of solver iterations helps making constraints stronger and also improves object stacking stability.

It is best to avoid small objects, as they are currently unstable. Ideally, objects should be at least 20 cm in diameter. If it is still necessary, setting the collision margin to 0, while generally not recommended, can help making small object behave more naturally.

When objects are small and/or move very fast, they can pass through each other. Besides what is mentioned above it's also good to avoid using mesh shapes in this case. Mesh shapes consist of individual triangles and therefore do not really have any thickness, so objects can pass through more easily. You can give them some thickness by increasing the collision margin.

## Combining Rigid Bodies with Other Simulations

Since the rigid body simulation is part of the animation system, it can influence other simulations just like the animation system can.

In order for this to work, the rigid body object needs to have a Collision Modifier. Simply click on Collision in the Physics tab.

## Scaling Rigid Bodies

Rigid body objects can be scaled, also during the simulation. This work well in most cases, but can sometimes cause problems.

If dynamic scaling is not needed, rigid body objects should have the scale applied.

## Rigid Body Constraint panel

### Type

The type of the constraint. Each type has some different settings.

#### Fixed

This constraint cause the two involved objects to move as one. Since the physics system

does have a tiny bit of slop in it, the objects do not move as rigidly as they would if they were part of the same mesh.

## Point

The objects are linked by a point bearing allowing any kind of rotation around the location of the constraint object, but no relative translation is permitted. The physics engine will do its best to make sure that the two points designated by the constraint object on the two constrained objects are coincident.

## Hinge

The hinge permits one degree of freedom between two objects. Translation is completely constrained. Rotation is permitted about the Z axis of the object hosting the Physics constraint (usually an empty, distinct from the two objects that are being linked). Adjusting the position and rotation of the object hosting the constraint allows you to control the anchor and axis of the hinge.

The Hinge is the only single-axis rotational constraint that uses the Z axis instead of the X axis. If something is wrong with your hinge, check your other constraints to see if this might be the problem.

## Slider

The Slider constraint allows relative translation along the X axis of the constraint object, but permits no relative rotation, or relative translation along other axes.

## Piston

A piston constraint permits translation along the X axis of the constraint object. It also allows rotation around the X axis of the constraint object. It is like a combination of the freedoms of a slider with the freedoms of a hinge.

## Generic

The X, Y, and Z axis constraints can be used to limit the amount of translation between the objects. Clamping the min/max to zero has the same effect as the Point constraint.

Clamping the relative rotation to zero keeps the objects in alignment. Combining an absolute rotation and translation clamp would behave much like the Fixed constraint.

Using a non-zero spread on any parameter allows it to rattle around in that range throughout the course of the simulation.

## Generic Spring

The generic spring constraint adds some spring parameters for the X/Y/Z axes to all the options available on the Generic constraint. Using the spring alone allows the objects to bounce around as if attached with a spring anchored at the constraint object. This is usually a little too much freedom, so most applications will benefit from enabling translation or rotation constraints.

If the damping on the springs is set to 1, then the spring forces are prevented from realigning the anchor points, leading to strange behavior. If your springs are acting weird, check the damping.

## Motor

The motor constraint causes translation and/or rotation between two entities. It can drive two objects apart or together. It can drive simple rotation, or rotation and translation (although it will not be constrained like a screw since the translation can be blocked by other physics without preventing rotation).

The rotation axis is the X axis of the object hosting the constraint. This is in contrast with the Hinge which uses the Z axis. Since the Motor is vulnerable to confusing perturbations without a matching Hinge constraint, special care must be taken to align the axes. Without proper alignment, the motor will appear to have no effect (because the hinge is preventing the motion of the motor).

## Rigid Body Constraint panel - Settings subpanel

### Enabled

Specifies whether the constraint is active during the simulation.

### Disable Collisions

Allows constrained objects to pass through one another.

### Breakable

Allows constraint to break during simulation. Disabled for the Motor constraint. This can be used to simulate destruction.

### Threshold

Impulse strength that needs to be reached before constraint breaks.

## Rigid Body Constraint panel - Limits subpanel

### Hinge

#### Angular

##### Z Angle

Limit rotation around Z axis.

## Slider

### Linear

#### *X Axis*

Enables/disables limit translation around X axis.

#### *X Lower*

Lower limit of X axis translation.

#### *Upper*

Upper limit of X axis translation.

## Piston

### Angular

#### *X Angle*

Enables/disables limit rotation around X axis.

#### *X Lower*

Lower limit of X axis rotation.

#### *Upper*

Upper limit of X axis rotation.

### Linear

#### *X Axis*

Enables/disables limit translation around X axis.

#### *X Lower*

Lower limit of X axis translation.

#### *Upper*

Upper limit of X axis translation.

## Generic + Generic Spring

### Angular

#### *X Axis/Y Axis/Z axis*

Enables/disables limit translation on X, Y or Z axis respectively.

## **Lower**

Lower limit of translation for X, Y or Z axis respectively.

## **Upper**

Upper limit of translation for X, Y or Z axis respectively.

## **Linear**

### **X Angle/Y Angle/Z Angle**

Enables/disables limit rotation around X, Y or Z axis respectively.

## **Lower**

Lower limit of rotation for X, Y or Z axis respectively.

## **Upper**

Upper limit of rotation for X, Y or Z axis respectively.

## Rigid Body Constraint panel - Motor subpanel

### **Angular**

#### **Target Velocity**

Target angular motor velocity.

#### **Max Impulse**

Maximum angular motor impulse.

### **Linear**

Target Velocity

Target linear motor velocity.

#### **Max Impulse**

Maximum linear motor impulse.

## Rigid Body Constraint panel - Objects subpanel

Pick the two objects that you want to constraint together.

## Rigid Body Constraint panel - Override Iterations subpanel

Override the default number of iterations. Allows to make constraints stronger (more iterations) or weaker (less iterations) than specified in the rigid body world.

### Iterations

Number of constraint solver iterations made per simulation step for this constraint.

## Rigid Body Constraint panel - Springs subpanel

### Generic Spring

The type generic spring allows you to limit the springs.

### Type

Which type of implementation to use.

### Angular

#### X/Y/Z Axis

Enables/disables springs translation on X, Y or Z axis respectively.

#### Stiffness

Spring Stiffness of the translation on X, Y or Z axis respectively. Specifies how “bendy” the spring is.

#### Damping

Spring Damping of the translation on X, Y or Z axis respectively. Amount of damping the spring has.

### Linear

#### X/Y/Z Angle

Enables/disables springs rotation around the X, Y or Z axis respectively.

#### Stiffness

Spring Stiffness of the rotation around the X, Y or Z axis respectively. Specifies how “bendy” the spring is.

#### Damping

Spring Damping of the rotation around the X, Y or Z axis respectively. Amount of damping the spring has.

## Physics

Gravity or collisions are real time physical effects. In the Physics tab you will find some methods to simulate such physical effects to use them in your images or movies. They allow objects to interact with each other. Like collisions. Or that wind forces bends some plant meshes. And much more.

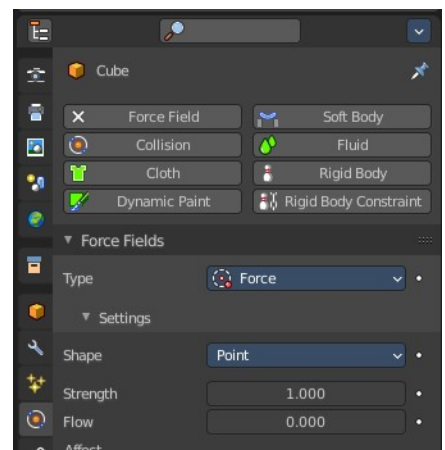

Not every object has a physics tab. And not all physics are available at the object types that has it available. A Bezier curve object for example has just Force Field, Soft Body and Rigid Body Constraints available.

By clicking at one of the buttons you will enable the physics type. And its settings will appear.

Active buttons will have an X at the front. By clicking at it you can remove the physics effect.

Some Physics types will add a modifier to the modifier stack. Cloth for example.

## Physics types

You can add up to eight different types of physics. There can be more than one physics type at the object.

### Force Field

As the name says, this physics type adds forces. Wind for example. And the forces can influence other physics types like particles, soft bodies, cloth and rigid bodies.

### Collision

Collision physics is meant for collisions. Particles, Soft Bodies and Cloth objects may collide with mesh objects. Boids try to avoid Collision objects.

### Cloth

Cloth is a physics effect that tries to simulate the motion and behavior of fabrics.

### Dynamic Paint

Dynamic paint is a modifier and physics system that can turn objects into paint canvases and brushes. With Dynamic Paint you can create vertex colors, image sequences or displacement. This makes many effects possible like, for example footsteps in the snow, raindrops that make the ground wet, paint that sticks to walls, or objects that gradually freeze.

### Soft Body

Soft body simulation is used for simulating soft deformable objects.

### Fluid

Fluid physics is used to simulate liquids.

## Rigid Body

Rigid bodies simulate the motion of solid objects. They can receive forces, gravity or acceleration for example. And allows collision without to deform them. Just mesh objects can have rigid bodies.

## Rigid Body Constraint

Rigid body constraint is used to connect two rigid bodies. This can be the position, or the rotation or scale.

# Simulation Nodes

The simulation is automatically cached during playback. For more information, please check out the Geometry Nodes Editor – Header – Simulation chapter.

## Calculate to Frame

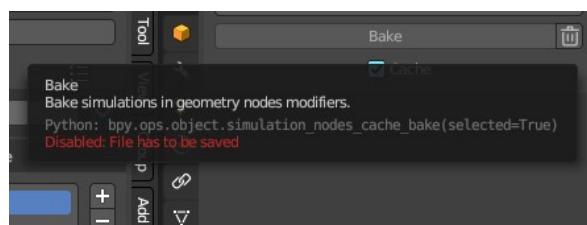

Calculate the simulations in Geometry Nodes modifiers from the start to current frame.

## Bake

Bake simulations in all geometry node modifiers to disk.

## Delete Cached Bake

The trashcan icon will erase the baked collection from disk.

## Cache

This checkbox toggles the feature to cache frames on playback. When you turn this off, then the automatic caching on playback will not bake to disk.

## Object Constraints

Object Constraints allows two objects to interact with each other. You can for example set the x position to the x position of another object with the Copy Location constraint.

You can have more than one constraint at an object.

There are four groups of object constraints:

**Motion Tracking** constraints constraints with Motion Tracking functionality.

**Transform** contains constraints around everything transform related.

**Tracking** contains constraints around animation functionality.

And **Relationship** contains constraints around relations.

The different color has no deeper sense. It helps with navigating in the list of constraints.

## General functionality

### Add

To add a constraint to an object, simply open the drop down menu, and choose the type of constraint that you want to add.

This will add the constraint to the list.

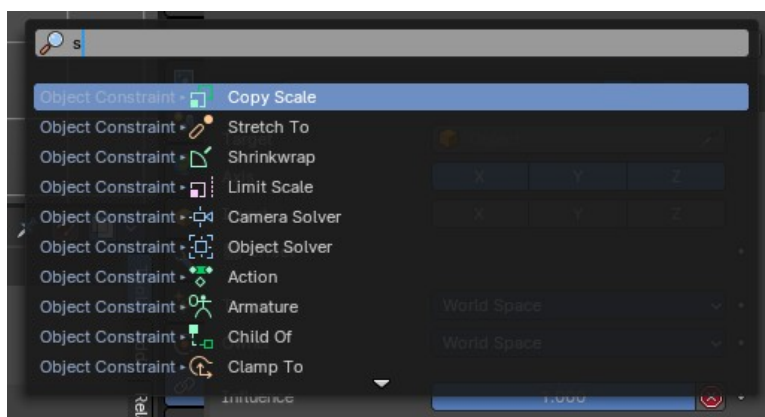

For some constraints you will also find menu items in the 3D view. The Inverse Kinematics / Add IK to Bone is such an example. It also fills in some vital information already in some cases, which you would need to choose by hand when you add the constraints in the constraint tab.

This menu entries exists to simplify the workflow. This menu entries are described in other chapters.

## Type to Search...

When the menu is open, you can press any key to start typing to search, this will filter the modifiers by name.

## Enable / Disable

You might want to disable a constraint temporarily. This can be done by clicking at the button with the eye icon in the header. To enable the constraint simply click it again.

## Apply

Applies the constraint. The current state becomes real. The constraint gets deleted.

## Dropdown menu

### Apply

Applies the constraint.

### Duplicate

Duplicates the constraint.

### Copy to Selected

Copies the constraint from the source to the target object. First select the source object, hold down shift and select the target object so that both are selected. Then perform Copy to Selected. The constraint will now also be at the target object.

### Move to First

Moves the constraint to the first place in the constraint list.

### Move to Last

Moves the constraint to the last place in the constraint list.

## Remove

To remove a constraint from the object simply click the close button up right in the header.

## Collapse panel

The whole constraints panel can be collapsed. Click at the arrow button up left in the header.

## Reorder

You can have more than one constraint in the list. And sometimes the order of the constraints is very important.

Grab the handler at the right and drag the constraint to the position where you want it to have.

## Animate Property

Some of the properties can be animated. Click at the animate property button at the right to add a keyframe.

## Object specific constraints

The Object Constraints tab does not contain all constraints. Some constraints are object specific. And appears in an own tab with this object selected. Bone constraints for example appears in the Bone Constraint tab.

Unfortunately you will still see the whole constraint list, and have to pick the bone constraints from there.

## Motion Tracking Constraints

This constraints gets used in Motion Tracking.

## Camera Solver

The Camera Solver constraint gives the owner of this constraint, the location and rotation of the «solved camera motion».

The «solved camera motion» is where Blender reconstructs the position of the physical, real-world camera, when it filmed the video footage, relative to the thing being tracked.

Note: This constraint only works after you have set up a minimum of eight markers and pressed Solve Camera

Motion. See motion tracking chapter.

## Active Clip

Receive tracking data from the active clip in the Movie Clip editor. If unchecked, an option appears to choose from the other clips.

## Constraint to F-Curve

Applies the constraint, and creates Keyframes for the transforms.

## Influence

The influence level of this constraint.

## Follow Track

This constraint makes objects have the same position at a frame as the track has. The motion of this object happens on a single plane defined by the camera and the original position of the object.

## Active Clip

Receive tracking data from the active movie clip in the Movie Clip editor. If unchecked, an option appears to choose from the other available clips.

## 3D Position

Use the 3D position of the track to parent to.

## Undistorted

Parent to the undistorted position of the 2D track.

## Frame Method

Defines how the footage is fitted in the camera frame.

## Camera

Select the camera to which the motion is parented to (if active an empty scene camera is used).

## Depth Object

If this object is set, constrained objects will be projected onto the surface of this depth object which can be used to create facial makeup visual effects.

## Constraint to F-Curve

Creates F-Curves for the object that copies the movement caused by the constraint.

## Influence

The influence level of this constraints.

## Object Solver

The Object Solver constraint gives the owner of this constraint, the location and rotation of the «solved object motion».

This can be used to add a mesh to video for example.

Note: This constraint only works after you have set up a minimum of eight markers and pressed Solve object Motion.

If it says Solve Camera Motion instead of Solve Object Motion then go into the Movie Clip Editor > Properties region > Objects and switch it from the camera, to an object.

## Active Clip

Receive tracking data from the active movie clip in the Movie Clip editor. If unchecked, an option appears to choose from the other available clips.

## Camera

Here you can choose the camera.

## Set Inverse / Clear Inverse

Set the connection for the object solver constraint inverse.

Clear the inversion.

## Constraint to F-Curve

Creates F-Curves for the object that copies the movement caused by the constraint.

## Influence

The influence level of this constraint.

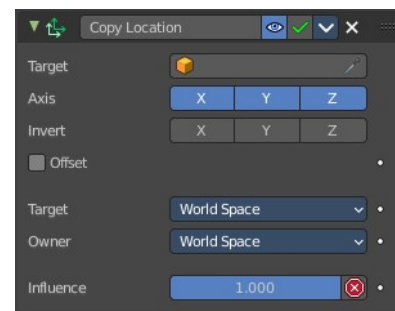

## Transform Constraints

This category contains transform constraints.

## Copy Location

The *Copy Location* constraint sets the position to the position of the target object.

### Warning

Using this constraint on a *connected* bone will have no effect. Because it is the parent's tip which controls the position of your owner bone's root.

## Target

Here you can choose the target object to copy the location from.

## Bone

If the *Target* is an *Armature*, then you have the optional choice to set an individual bone as *Target*.

## Head/Tail

If the target is a bone, then here you can adjust where along this bone the target point lies.

## Vertex Group

If the *Target* is a *Mesh*, then you have the optional choice to set a *Vertex Group* as target.

## X, Y, Z

Here you can choose which axes to constraint.

## Invert

Inverts the coordinate input. Positive becomes negative, and vice versa.

## Offset

Add an offset from the original position to the target position.

## Target Space for Target and Owner

Here you can choose the target space and its coordinate system to use for calculation. The local space uses local axis, the world space global axis. Custom space allows you to use custom data. Like a vertex group of an object.

## Influence

The influence level of this constraint.

## Copy Rotation

The *Copy Rotation* constraint sets the rotation to the rotation of the target object.

### Target

Here you can choose the target object to copy the rotation from.

## Vertex Group

If the *Target* is a *Mesh*, a new field is displayed offering the optional choice to set a *Vertex Group* as target.

## Bone

If the *Target* is an *Armature*, a new field is displayed offering the optional choice to set an individual bone as *Target*.

## X, Y, Z

These buttons control which axes are constrained - by default, all three are on.

## Invert

Inverts the coordinate input. Positive becomes negative, and vice versa.

## Offset

Add an offset from the original position to the target position.

## Target Space for Target and Owner

Here you can choose the target space and its coordinate system to use for calculation. The local space uses local axis, the world space global axis. Custom space allows you to use custom data. Like a vertex group of an object.

## Influence

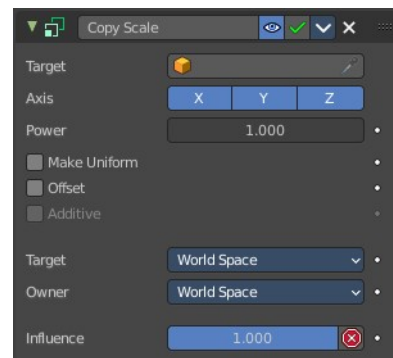

The influence level of this constraint.

## Copy Scale

The *Copy Scale* constraint sets the size to the size of the target object.

### Target

Here you can choose the target object to copy the size from.

### Vertex Group

If *Target* is a *Mesh*, a new field is displayed offering the optional choice to set a *Vertex Group* as target.

### Bone

If *Target* is an *Armature*, a new field is displayed offering the optional choice to set an individual bone as *Target*.

### X, Y, Z

These buttons control which axes are constrained - by default, all three are on.

### Offset

Add an offset from the original scale to the target scale.

### Additive

Use Addition instead of Multiplication to combine scale. This is a compatibility feature to Blender 2.79 and Bforartists 1

### Target Space for Target and Owner

Here you can choose the target space and its coordinate system to use for calculation. The local space uses local axis, the world space global axis. Custom space allows you to use custom data. Like a vertex group of an object.

## Influence

The influence level of this constraint.

## Copy Transforms

The *Copy Transform* constraint copies the whole transform values from the target object. Location, Rotation and Scale.

### Target

Here you can choose the target object to copy the location from.

### Vertex Group

If *Target* is a *Mesh*, a new field is displayed offering the optional choice to set a *Vertex Group* as target.

### Bone

If the *Target* is an *Armature*, a new field is displayed offering the optional choice to set an individual bone as *Target*.

### Head/Tail

If the target is a bone, then here you can adjust where along this bone the target point lies.

### Remove Target Shear

Remove shear from the target transformation before combining.

### Mix

The mix mode specifies how the copied and existing transformations are combined.

### Target Space for Target and Owner

Here you can choose the target space and its coordinate system to use for calculation. The local space uses local axis, the world space global axis. Custom space allows you to use custom data. Like a vertex group of an object.

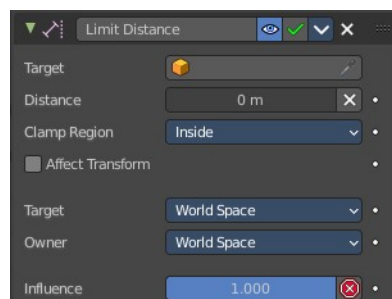

### Influence

The influence level of this constraint.

## Limit Distance

The *Limit Distance* constraint constraints either outside, inside, or at the surface of a sphere centered at the target object.

## Target

Here you can choose the target object.

## Vertex Group

If *Target* is a *Mesh*, a new field is displayed offering the optional choice to set a *Vertex Group* as target.

## Bone

If the *Target* is an *Armature*, a new field is displayed offering the optional choice to set an individual bone as *Target*.

## Head/Tail

If the target is a bone, then here you can adjust where along this bone the target point lies.

## Distance

This numeric field sets the limit distance, i.e. the radius of the constraining sphere.

## Reset Distance

When clicked, this small button will reset the *Distance* value, so that it corresponds to the actual distance between the owner and its target (i.e. the distance before this constraint is applied).

## Clamp Region

The *Limit Mode* drop-down menu allows you to choose how to use the sphere defined by the *Distance* setting and target's center:

### *Inside*

The owner is constrained *inside* the sphere.

### *Outside*

The owner is constrained *outside* the sphere.

### *Surface*

The owner is constrained *on the surface* of the sphere.

## Target Space for Target and Owner

Here you can choose the target space and its coordinate system to use for calculation. The local space uses local axis, the world space global axis. Custom space allows you to use custom data. Like a vertex group of an object.

## Influence

The influence level of this constraint.

## Limit Location

This constraint restricts the amount of allowed translations along each axis, through lower and upper bounds.

The limits for an object are calculated from its center. Te limits of a bone are calculated from its root.

### Minimum X Y Z

Restrict the minimum location. You can adjust the value in the edit box below.

### Maximum X Y Z

Restrict the maximum location. You can adjust the value in the edit box below.

### For Transform

The constraint limits the location. The values in the transform panel can still change above this limit though. With this option ticked the transform values are also clamped.

### Convert

Calculate the constraint in local space or world space.

## Influence

The influence level of this constraint.

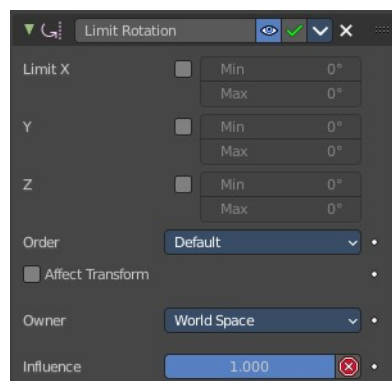

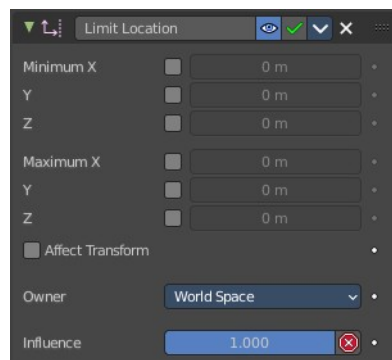

## Limit Rotation

This constraint restricts the amount of allowed rotation along each axis, through lower and upper bounds.

The limits for an object are calculated from its center. Te limits of a bone are calculated from its root.

### Limit X Y Z

Restrict the rotation. You can adjust the minimum and maximum value in the edit boxes below.

## Order

Euler Order. Allows to specify the order of the euler angles.

## Affect Transform

The constraint limits the rotation. The values in the transform panel can still change above this limit though. With this option ticked the transform values are also clamped.

## Owner Space

Calculate the constraint in custom space, local space or world space.

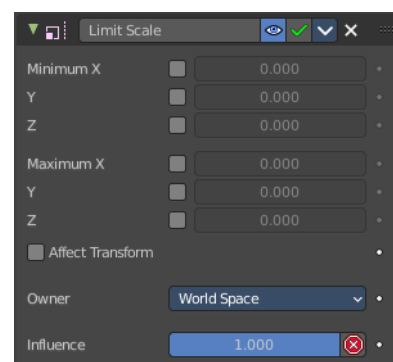

## Influence

The influence level of this constraint.

## Limit Scale

This constraint restricts the amount of allowed scale along each axis, through lower and upper bounds.

The limits for an object are calculated from its center. Te limits of a bone are calculated from its root.

## Minimum X Y Z

The minimum size. You can adjust the value in the edit boxes below.

## Maximum X Y Z

The maximum size. You can adjust the value in the edit boxes below.

## For Transform

The constraint limits the location. The values in the transform panel can still change above this limit though. With this option ticked the transform values are also clamped.

## Convert

Calculate the constraint in local space or world space.

## Influence

The influence level of this constraint.

## Maintain Volume

The *Maintain Volume* constraint limits the volume of a mesh or a bone to a given ratio of its original volume.

## Free X / Y / Z

The free-scaling axis of the object.

## Volume

The bone's rest volume.

## Owner Space

Calculate the constraint in local space or world space. Custom space allows you to use custom data. Like a vertex group of an object.

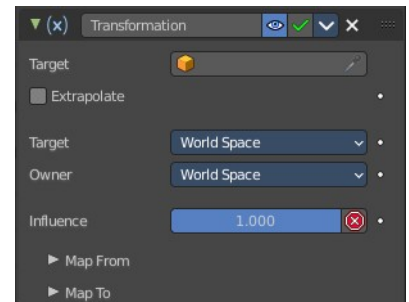

## Influence

The influence level of this constraint.

## Transformation

The Transformation constraint allows you to map one type of transform properties (i.e. location, rotation or scale) of the target, to the same or another type of transform properties of the owner, within a given range of values.

### Warning

Note that:

- When mapping transform properties to location (i.e. *Loc*, *Destination* button is enabled), the owner's existing location is added to the result of evaluating this constraint (exactly like when the *Offset* button of the *Copy Location constraint* is enabled...).
- Conversely, when mapping transform properties to rotation or scale, the owner's existing rotation or scale is overridden by the result of evaluating this constraint.
- When using the rotation transform properties of the target as input, whatever the real values are, the constraint will always “take them back” into the  $-180, 180$  range (e.g. if the target has a rotation of 420 around its X axis, the values used as X input by the constraint will be  $((420 + 180) \bmod 360) - 180 = 60 - \dots$ ). This is why this constraint is not really suited for gears!
- Similarly, when using the scale transform properties of the target as input, whatever the real values are, the constraint will always take their absolute values (i.e. invert negative ones).
- When a *min* value is higher than its corresponding *max* one, both are considered equal to the *max* one. This implies you cannot create “reversed” mappings...

## Target

Here you can choose the target object.

## Vertex Group

If the *Target* is a *Mesh*, a new field is displayed offering the optional choice to set a *Vertex Group* as target.

## Bone

If the *Target* is an *Armature*, a new field is displayed offering the optional choice to set an individual bone as *Target*.

## Extrapolate

With this option enabled the *min* and *max* values are no longer strict limits, but rather “markers” defining a proportional (linear) mapping between input and corresponding output values.

## Target Space

Space that the target is evaluated in.

## Owner Space

Calculate the constraint in local space or world space. Custom space allows you to use custom data. Like a vertex group of an object.

## Influence

The influence level of this constraint.

## Map From subpanel

### *Location Rotation Scale*

A tab to switch between the available location, rotation and scale values.

### X Y Z

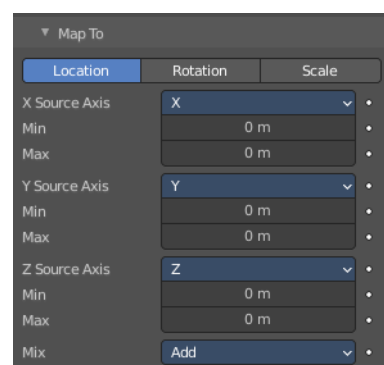

The transform values. Here you can edit the minimum and maximum values for the source object.

## Map To subpanel

### *Location Rotation Scale*

A tab to switch between the available location, rotation and scale values.

## X Source Axis

What axis to use for the X Source constraint.

### Min Max

Edit the minimum and maximum values for the source object.

## Y Source Axis

What axis to use for the Y Source constraint.

### Min Max

Edit the minimum and maximum values for the source object.

## Z Source Axis

What axis to use for the Z Source constraint.

### Min Max

Edit the minimum and maximum values for the source object.

## Mix

The location mix mode.

## Transform cache

The Transform Cache Constraint allows you to stream animations from Alembic files. The data that is read is at transformation matrix level (for example rigid bodies, or camera movements).

Transform Cache constraints are automatically added to objects with animated transforms.

For time-varying meshes (means deforming animations), the Mesh Sequence Cache modifier is used.

## Cache File property

Load the Alembic file.

### Dara Browser

A list of available alembic files that are already loaded.

### ***Edit Box***

The name of the alembic file.

### ***Fake User***

Keep the file in the scene even when it is not used.

### ***Open Cache File***

Load an alembic file.

### ***Remove***

Remove the alembic file as the active file. The file will remain in the scene until you purge it, close and reload the scene. Given that it has no fake user assigned to keep it in the scene anyways.

### **File Path**

The path to the Alembic file.

### **Sequence**

Whether or not the cache is separated in a series of files.

### ***Refresh Active***

Update the files and paths.

### **Object Path**

The path to the Alembic object inside the archive.

### **Influence**

Controls the percentage of affect the constraint has on the object. See common constraint properties for more information.

## **Time Subpanel**

### **Sequence**

Whether or not the cache is separated in a series of files.

### **Override Frame**

Whether to use a custom frame for looking up data in the cache file, instead of using the current scene frame.

### ***Frame***

The time to use for looking up the data in the cache file, or to determine which to use in a file sequence.

## Frame Offset

Define a frame offset to the current frame.

## Render Procedural subpanel

### ***Use Render Engine Procedural***

This feature is just available for Cycles, and just in an experimental state.

Display boxes as placeholders in the viewport.

### ***Use Prefetch***

This feature is just available for Cycles, and just in an experimental state.

When enabled, the Cycles procedural will preload animation data for faster update.

### ***Prefetch Cache Size***

This feature is just available for Cycles, and just in an experimental state.

Memory usage limit for the cache. If the data size does not fit the renderer is aborted. 0 disables the feature.

## Velocity subpanel

### ***Velocity Attribute***

The name of the Alembic attribute used for generating motion blur data. By default, this is .velocities which is standard for most Alembic files.

### ***Velocity Unit***

Defines how the velocity vectors are interpreted with regard to time.

## Tracking Constraints

## Clamp To

The *Clamp To* constraint clamps an object to a curve. So you need a curve object as the target.

## Target

Here you can choose the target object.

## Main Axis

Auto clamps to all three axis. X , Y, Z maps just to one axis,.

## Cyclic

With cyclic enabled the object will jump from end point to start point once it has reached the end.

## Influence

The influence level of this constraint.

## Damped Track

Damped track makes the object always look at the target object. For example a camera always looking at an armature

## Target

Here you can choose the target object.

## Vertex Group

If the *Target* is a *Mesh*, a new field is displayed offering the optional choice to set a *Vertex Group* as target.

## Bone

If the *Target* is an *Armature*, a new field is displayed offering the optional choice to set an individual bone as *Target*.

## Head/Tail

If the target is a bone, then here you can adjust where along this bone the target point lies.

## To

The axis to use to point towards the target object. For a camera you might want to use -Z

## Influence

The influence level of this constraint.

## Locked Track

Similar to Damped Track. Locked track makes the object always look at the

target object. For example a camera always looking at an armature. But here you can lock single axis.

Note, you cannot lock the axis where you look at. The constraint will show the name red then.

## Target

Here you can choose the target object.

## Vertex Group

If the *Target* is a *Mesh*, a new field is displayed offering the optional choice to set a *Vertex Group* as target.

## Bone

If the *Target* is an *Armature*, a new field is displayed offering the optional choice to set an individual bone as *Target*.

## Head/Tail

If the target is a bone, then here you can adjust where along this bone the target point lies.

## To

The axis to use to point towards the target object. For a camera you might want to use -Z

## Lock

The axis that you want to lock.

## Influence

The influence level of this constraint.

## Stretch To

Stretch To makes the object always look at the target object. For example a cube always looking at another cube. And makes it stretch when the distance changes.

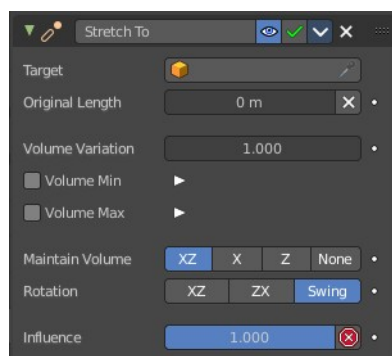

With bones, the “volumetric” variation scales them along their own local axes (remember that the local Y axis of a bone is aligned with it, from root to tip).

## Target

Here you can choose the target object.

## Vertex Group

If the *Target* is a *Mesh*, a new field is displayed offering the optional choice to set a *Vertex Group* as target.

## Bone

If the *Target* is an *Armature*, a new field is displayed offering the optional choice to set an individual bone as *Target*.

## Head/Tail

If the target is a bone, then here you can adjust where along this bone the target point lies.

## Rest Length

Here you can define the rest distance between the owner and its target. The rest length is the distance at which there is no deformation (stretching) of the owner.

## Reset

Resets the Rest Length.

## Volume Min / Volume Max

Here you can control the amount of “volume” variation proportionally to the stretching amount. Note that the 0.0 value is not allowed.

## Smooth

Shows when either the volume min or volume max is ticked. Strength of volume stretching clamping.

## Volume

Here you can adjust which of the X and/or Z axes should be affected to preserve the virtual volume while stretching along the Y axis. The NONE button disables the volumetric features.

## Plane

Here you can control which of the X or Z axes should be as much as possible aligned with the global Z axis, while tracking the target with the Y axis.

## Influence

The influence level of this constraint.

## Track To

Track To makes the object always look at the target object. For example a cube always looking at another cube. Or a camera looking at a mesh.

## Target

Here you can choose the target object.

## Vertex Group

If the *Target* is a *Mesh*, a new field is displayed offering the optional choice to set a *Vertex Group* as target.

## Bone

If the *Target* is an *Armature*, a new field is displayed offering the optional choice to set an individual bone as *Target*.

## Head/Tail

If the target is a bone, then here you can adjust where along this bone the target point lies.

## To

The axis to use to point towards the target object.

## Up

The axis that points upwards

## Target Z

Constrain the UP direction to the target's Z axis instead of the World Z Axis.

## Target Space for Target and Owner

Here you can choose the target space and its coordinate system to use for calculation. The local space uses local axis, the world space global axis. Custom space allows you to use custom data. Like a vertex group of an object.

## Influence

The influence level of this constraint.

# Relationship Constraints

## Action

The Action constraints allows you control an *Action* using the animated transformations of another object. For example move a cube when

another cube moves by animation, without the need to record this movement by a keyframe. There needs to be an animation in the scene, not necessarily at the target object, which is used as the Action for the constraint.

The constraint accepts the *Mesh* action type. But only the *Object*, *Pose* and *Constraint* types are really working, since constraints can only affect objects' or bones' transform properties, and not meshes' shapes.

Only the object transformation (location, rotation, scale) is affected by the action. Keyframes for other properties are ignored. The constraints does not influence them.

## Example:

Create a cube. Animate it to create the needed action. Move from a to b for example. And record the keyframes. This will create an action that is now available to the constraint.

Moving the target in the  $[0.0, 2.0]$  range along its X axis maps the action content on the owner in the  $[0, 100]$  frame range. This will mean that when the target's X property is  $0.0$  the owner will be as if in frame  $0$  of the linked action. With the target's X property at  $1.0$  the owner will be as if in frame  $50$  of the linked action, etc.

## Target

Here you can choose the target object.

### Vertex Group

If the *Target* is a *Mesh*, a new field is displayed offering the optional choice to set a *Vertex Group* as target.

### Bone

If the *Target* is an *Armature*, a new field is displayed offering the optional choice to set an individual bone as *Target*.

### Evaluation Time

Interpolate between action start and endframe by using the slider value instead of using the target object.

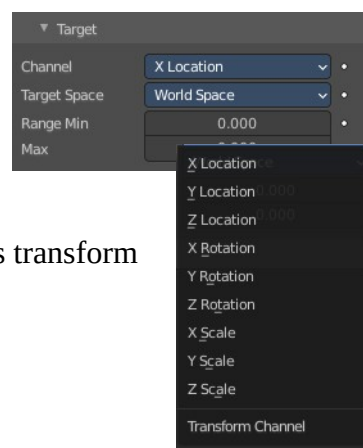

### Influence

The influence level of this constraint.

## Target subpanel

### Channel

The transform channel allows you to choose in which space to evaluate its target's transform

properties.

## Target Space

The space in which the target is transformed in.

World space transforms in the world space.

Local space transforms in the local space.

Custom space transforms in the space of the target object. You need to pick the target object.

## Target Range Min / Max

The lower and upper bounds of the driving transform property value. By default, both values are set to 0.0

Note:

- When using a rotation property as “driver”, these values are “mapped back” to the -180.0 , 180.0 range.
- When using a scale property as “driver”, these values are limited to null or positive values.

## Action subpanel

## Action

Here you can choose the action that you want to use. Available actions appears in the drop down list.

## Object Action

This is for bones only. This option will make the constrained bone use the “object” part of the linked action, instead of the “same-named pose” part. This allows you to apply the action of an object to a bone.

## Frame Start / End

The starting and ending frames of the action to be mapped.

Note:

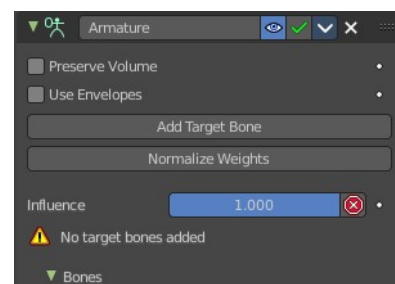

- These values must be strictly positive.
- By default, both values are set to 0 which disables the mapping (i.e. the owner just gets the properties defined at frame 0 of the linked action...).

## Notes

- When the linked action affects some location properties, the owner’s existing location is added to the result of evaluating this constraint (exactly as when the *Offset* button of the *Copy Location constraint* is enabled...).
- When the linked action affects some scale properties, the owner’s existing scale is multiplied with the result of evaluating this constraint.
- When the linked action affects some rotation properties, the owner’s existing rotation is overridden by the result of evaluating this constraint.
- Unlike usual, you can have a *Start* value higher than the *End* one, or a *Min* one higher than a *Max* one: this will reverse the mapping of the action (i.e. it will be “played” reversed...), unless you have both sets reversed, obviously!
- When using a *Constraint* action, it is the constraint *channel’s names* that are used to determine to which constraints of the owner apply the action. E.g. if you have a constraint channel named “trackto\_empt1”, its keyed *Influence* and/or *Head/Tail* values (the only ones you can key) will be mapped to the ones of the owner’s constraint named “trackto\_empt1”.
- Similarly, when using a *Pose* action (which is obviously only meaningful and working when constraining a bone!), it is the bone’s name that is used to determine which bone *channel’s names* from the action to use (e.g. if the constrained bone is named “arm”, it will use and only use the action’s bone channel named “arm”...). Unfortunately, using a *Pose* action on a whole armature object (to affect all the keyed bones in the action at once) won’t work...
- Note also that you can use the *pose library feature* to create/edit a *Pose* action data-block... just remember that in this situation, there’s one pose per frame!

## Armature

Armature is the constraint version of the Armature Modifier. It reproduces the weight-blended bone transformations and applies it to its owner orientation. It can be used like a variant of the Child Of constraint that can handle multiple parents at once, but requires all of them to be bones.

### Preserve Volume

Tries to preserve the volume when deforming the mesh.

### Use Envelopes

Multiply the weights by envelope for all bones instead of vertex group based blending. The specified weights are still used, and only the listed bones are considered.

### Add Target Bone

Add a target bone. By clicking two edit boxes becomes available. You can add multiple armatures and bones here.

## Normalize Weights

Normalize the weights of all target bones.

## Influence

The influence level of this constraint.

## Bones subpanel

When you add a bone with the Add Target Bone, then you create a property in this panel.

### First Edit Box

Here you select the armature.

### Second Edit Box

Here you select the bone.

### Remove Target

Remove the target. Resets Add Target Bone.

### Blend Weight

Blending Weight of this bone.

## Child Of

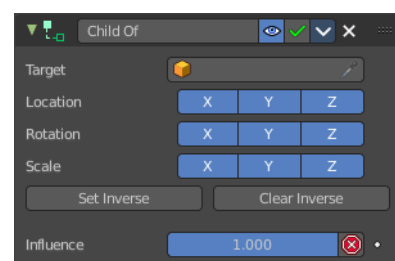

This constraint allows you to set a parent to this object. By using more than one constraint you can have more than one parent object here, and control the influence by the Influence slider. You can also just parent the movement of a specific axis.

### Target

Here you can choose the target object.

### Vertex Group

If the *Target* is a *Mesh*, a new field is displayed offering the optional choice to set a *Vertex Group* as target.

### Bone

If the *Target* is an *Armature*, a new field is displayed offering the optional choice to set an individual bone as *Target*.

## Location, Rotation, Scale

Activate the parenting for the corresponding axis.

## Set Inverse / Clear Inverse

Set the connection for the object solver constraint inverse.

Clear the inversion.

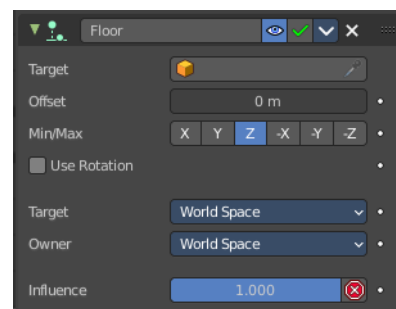

## Influence

The influence level of this constraint.

## Floor

The Floor constraints allows to set an object as a floor or wall that cannot be passed by the object.

Note that the center of the object is calculated as the collision point, not the surface. Means a cube with the pivot in the center can still sink half into a ground plane. This can be adjusted with the Offset value.

## Target

Here you can choose the target object.

## Vertex Group

If the *Target* is a *Mesh*, a new field is displayed offering the optional choice to set a *Vertex Group* as target.

## Bone

If the *Target* is an *Armature*, a new field is displayed offering the optional choice to set an individual bone as *Target*.

## Sticky

The object sticks at its position at contact. For example, it cannot slide around on the surface of a plane any more.

## Use Rotation

Take the target's rotation into account. This allows you to have a "floor" plane of any orientation you like, not just the global XY, XZ and YZ ones...

## Offset

Here you can define an offset from the pivot to the ground plane object.

## Min / Max

Here you define which side of the target object will be the floor.

By default, these normals are aligned with the global axes. If you enable Use Rotation (see above), they will be aligned with the local target's axes.

## Target Space for Target and Owner

Here you can choose the target space and its coordinate system to use for calculation. The local space uses local axis, the world space global axis. Custom space allows you to use custom data. Like a vertex group of an object.

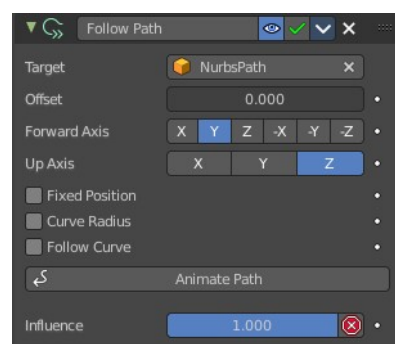

## Influence

The influence level of this constraint.

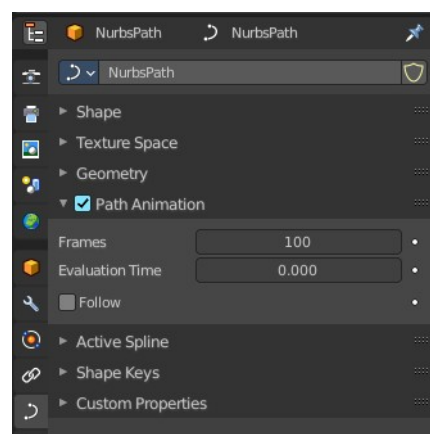

## Follow Path

Makes the object follow a curve path. This constraint requires a Bezier or Nurbs Curve. Follow Path is an animation only constraint.

The movement happens in the global world.

Click at Animate Path to create the animation. When you play the animation, then the object will move along the path now. The path length can be adjusted in the Path Animation panel of the curve. Here you can see that the value behind evaluation time is now green. And there is a keyframe symbol behind the edit box. Adjust the number of frames to your needs.

## Target

Choose the target path.

## Offset

The number of frames to offset from the “animation” defined by the path. It starts by default from frame 1.

## Forward Axis

The axis that points forward at the path.

## Up Axis

The axis that points upwards.

## Fixed position

Object will stay locked to a single point somewhere along the length of the curve regardless of time.

## Curve Radius

Objects scaled by the curve radius. See Curve Editing.

## Follow Curve

When this option is activated, the owner's rotation is modified by:

### *Forward*

The axis of the object that has to be aligned with the forward direction of the path (i.e. tangent to the curve at the owner's position).

### *Up*

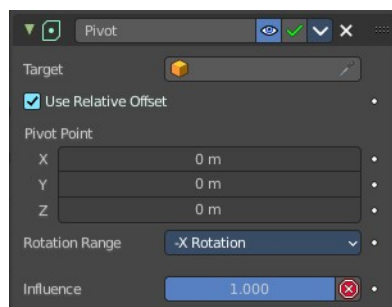

The axis of the object that has to be aligned (as much as possible) with the world Z axis. In fact, with this option activated, the behavior of the owner shares some properties with the one caused by a Locked Track constraint, with the path as "axle", and the world Z axis as "magnet".

## Animate Path

Add a default animation for the path constraint if it is not animated already.

## Pivot

The *Pivot* constraint allows the owner to rotate around a target object.

## Target

Here you can choose the target object.

## Vertex Group

If the *Target* is a *Mesh*, a new field is displayed offering the optional choice to set a *Vertex Group* as target.

## Bone

If the *Target* is an *Armature*, a new field is displayed offering the optional choice to set an individual bone as *Target*.

## Head/Tail

If the target is a bone, then here you can adjust where along this bone the target point lies.

## Use Relative Offset

Offset will be an absolute point in space instead of relative to the target.

## Pivot Offset X / Y / Z

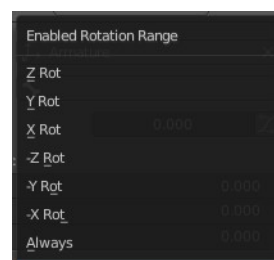

Here you can adjust an offset.

## Rotation Range

Enable rotation range for specific axis.

## Influence

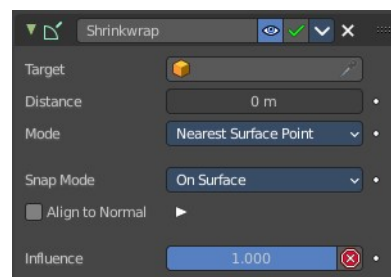

The influence level of this constraint.

## Shrinkwrap

The Shrinkwrap constraint allows you to snap objects to the surface of mesh objects. The target object has to be a Mesh object. Other object types does not work.

The snap point is the pivot point of the object.

## Distance

Here you can adjust an offset.

## Shrinkwrap Mode

Here you can choose between different shrink-wrap methods.

## Target Normal Project

Target the nearest target surface along the interpolated vertex normals of the target.

## Nearest Vertex

Target the nearest vertex at the target.

## Project

Target the nearest surface point along a given axis.

### Project Axis

Here you can define the axis

### Space

Here you can define the space that gets used for this axis.

### Distance

Limit the distance used for projection. Zero disables the Project Distance.

### Project Opposite

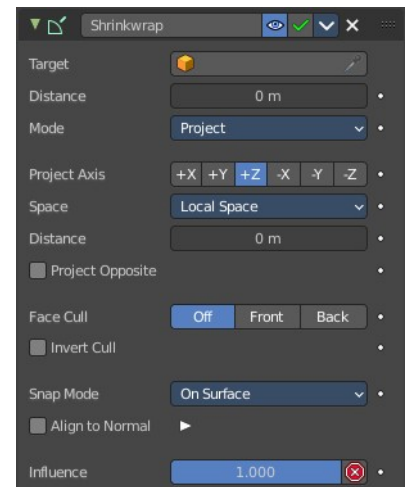

Project in both specified and opposite directions.

### Face Cull

Stop vertices from projecting to a face on the target when facing towards or away.

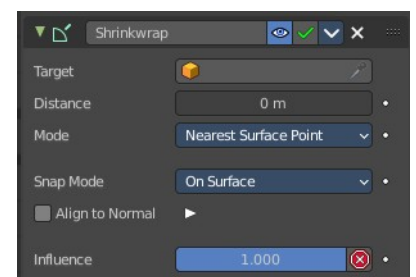

### Invert Cull

Invert the face cull mode.

## Nearest Surface Point

Target the nearest surface point.

## Snap Mode

## Align to Normal

Align a specified axis to the surface normal.

## Influence

The influence level of this constraint.

## Empty panel

Empties are objects without additional geometry. They do not render. A use case is that you use empties as handlers for a rigged character.

### Display As

Empties have graphical elements to display the location. In this drop down list you can choose the shape of this graphical element.

Further display settings can be found in the Object Properties tab in the Viewport Display panel.

### Size

The size of the graphical element.

## Image

Empties can display images. This images can be used to create reference images to model along. The image is always displayed, independent of the 3D display mode.

### **Offset X, Y**

Offset the image origin. 1.0 represents the width/height of the image.

### **Depth**

#### **Default**

Use normal depth behavior.

#### **Front**

Always display on top of other objects.

#### **Back**

Always display behind of other objects.

### **Side**

#### **Both**

Display both the front and back of the empty.

#### **Front**

Only display the front of the image.

#### **Back**

Only display the back of the image.

### **Show in**

#### **Orthographic**

Show in orthographic view.

#### **Perspective**

Show in perspective view.

#### **Only Axis Aligned**

Only displays the image contents when the view is aligned with the object's local axis.

### **Transparency**

Use alpha blending instead of alpha-test. The image then blends with the background but can have depth sorting artifacts.

## Opacity

The opacity.

## Image panel

When you choose an empty of type Image then this panel with further settings appears.

## Image property

### Image Browser

A list of available images in the scene.

### Open

When no image is loaded the open button is displayed. Open an image opens the file browser to load an image.

### Name

The name of the currently active image.

### Fake User

Keep this image in the scene even if it has no user.

### Open Image

Open image opens the file browser to load an image.

## Source

What image type to choose.

## Source Type Single Image

### Path edit box

### Pack

With this button you can pack the movie or the image sequence into the blend file. It gets packed when you

save the blend file the next time.

### Path edit box

See and edit the path to your movie or image sequence files.

### Open

Open a new movie or image sequence files. A file dialog will appear.

### Refresh

Reread the movie or image sequence files.

### Color Space

Choose the color space type for the movie or image sequence files.

---

## Source Type Movie + Image Sequence

### Path edit box

### Pack

With this button you can pack the movie or the image sequence into the blend file. It gets packed when you save the blend file the next time.

### Path edit box

See and edit the path to your movie or image sequence files.

### Open

Open a new movie or image sequence files. A file dialog will appear.

### Refresh

Reread the movie or image sequence files.

## **Info string**

Some information about the currently loaded movie. Frames, resolution and color space.

---

### **Frames**

The number of frames of the movie or image sequence.

### **Start**

The start frame of the movie or image sequence

### **Offset**

Offset the number of the frame to use in the animation. -1 means off.

### **Cyclic**

Cycle the images in the movie.

### **Auto Refresh**

Always refresh image on frame changes.

---

## **Color Space**

Choose the color space type for the movie or image sequence files.

## **Source Type Generated**

### **X / Y**

The image width and height.

### **Float Buffer**

Use a floating point buffer. 8 Bit images uses integers. 32 Bit works with floats.

## **Generated Type Blank**

This type displays an image with one blank color.

## Color

The color of the blank image.

## Generated Type UV Grid

This type displays a with a black and white checker texture but colored dots.

## Generated Type Color Grid

This type displays a with a colored checker texture with numbers.

## Color Space

Choose the color space type for the image.

## Source Type Udim

UDIM is an enhancement to the UV mapping and texturing workflow. And does not belong here. But in the UV Editor. It is just in the list because it shares the same menus with the UV Editor.

You can load a UDIM file. But it will just display the first tile of the UDIM image. And there is no way to adjust the UDIM settings since they are in the UV Editor, in Edit mode. And Empties have no Edit mode.

## Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

## Add

Adds a new property.

## Edit

Opens a panel where you can adjust the settings for the custom property.

## Remove

Removes the property.

## Sound panel

### Sound property

Note that sound files just loads as Mono files.

### Data Browser

A list of available sounds in the scene.

### Open

When no sound is loaded the open button is displayed. Open opens the file browser to load an audio file.

## Name

The name of the currently active image.

## Fake User

Keep this image in the scene even if it has no user.

## Open Sound Mono

Open a sound file as mono. You can load stereo files too when you untick Mono in the import settings.

## Import settings

### *Relative Path*

Load the file with a relative path.

### *Cache*

The whole sound will be decoded and the raw audio data will be buffered in memory.

### *Mono*

For any 3D audio or panning effects the sound source has to be single channel, otherwise it's assumed that the 3D audio and panning information is already present in the multichannel file. Enable this if you want to use those effects for a file with multiple channels.

## Remove

Remove the sound file. Note that the file is not deleted, but removed as the active sound file.

## Mute

Toggles whether or not the sound can be heard.

## Volume

Adjust the loudness of the sound.

## Pitch

Can be used to bend the pitch of the sound to be either deeper or higher. This basically changes the playback speed of the sound which also results in a pitch change.

## Distance panel

Distance relevant settings.

## Volume Min

The minimum volume for the farthest distance.

## Max

The maximum volume for the closest distance.

## Attenuation

How strong the distance affects the volume. This value is dependent of the chosen Distance model in the Scene properties in the Audio panel.

## Max Distance

The distance maximum.

## Distance Reference

The distance at which the volume is 100%.

# Cone panel

Directionality relevant settings.

There are two cones for an audio source that defines the direction of the sound. An inner and an outer cone. The angles represent their opening angles.

360° mean the cone is fully open and there's no directionality anymore. Inside the inner cone the volume is 100% (1.0), outside the outer cone the volume is, whatever one sets for the outer cone volume and the volume between those two cones, linearly interpolated between this two volumes.

## Angle Outer

Angle of the outer cone in degrees. Outside this cone, the volume is equal to the Outer volume.

## Inner

Angle of the inner cone in degrees. Inside the cone, the volume is 100%.

## Outer Cone Volume

Volume outside the outer cone.

## Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

### Add

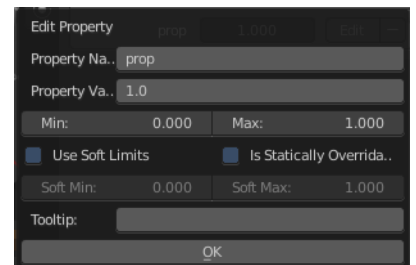

Adds a new property.

### Edit

Opens a panel where you can adjust the settings for the custom property.

### Remove

Removes the property.

## Lens panel

### Type

How to display the content in the camera view.

### Perspective

Displays the content with perspective distortions.

### Lens Unit

What lens unit to use. Millimeters or Field of View as an angle.

### Focal Length

With Lens Unit Millimeters. The focal length controls the amount of zoom, i.e. the amount of the scene which is visible all at once. Longer focal lengths result in a smaller Field of View (more zoom), while short focal lengths allow you to see more of the scene at once (larger Field of View, less zoom). Focal length is adjusted in millimeters like in a real camera.

### Field of View

With Lens Unit Field of View. Field of View is adjusted in degrees. But has the same purpose than Focal Length. Smaller angle means small field of view more zoom. Higher angle means larger field of view and less zoom.

### Orthographic

Displays the content in parallel projection.

### Orthographic Scale

The camera lens angle influences the zoom factor.

### Panoramic

Panoramic cameras just works with Cycles. Panoramic allows you to render equirectangular, fish eye and mirror ball images. Note that the result is not displayed in the viewport.

## Lens Unit

What lens unit to use. Millimeters or Field of View as an angle.

## Focal Length

With Lens Unit Millimeters. The focal length controls the amount of zoom, i.e. the amount of the scene which is visible all at once. Longer focal lengths result in a smaller Field of View (more zoom), while short focal lengths allow you to see more of the scene at once (larger Field of View, less zoom). Focal length is adjusted in millimeters like in a real camera.

## Field of View

With Lens Unit Field of View. Field of View is adjusted in degrees. But has the same purpose than Focal Length. Smaller angle means small field of view more zoom. Higher angle means larger field of view and less zoom.

## Shift X / Y

Allows the adjustment of vanishing points. Vanishing points refer to the positions to which parallel lines converge.

Note! Using lens shift is equivalent to rendering an image with a larger FOV and cropping it off-center.

## Clip Near and Far

The closest and farthest distance in which the scene geometry gets displayed. Any objects outside this range still influence the image indirectly. Further light bounces are not clipped. But they are not displayed directly.

Note! For viewport rendering, setting clipping distances to limited values is important to ensure sufficient rasterization precision. Ray tracing renders do not suffer from this issue so much, and as such more extreme values can safely be set.

Tip! When Limits in the Viewport Display panel is enabled, the clip bounds will be visible as two yellow connected dots on the camera's line of sight

# Depth of Field panel

Depth of Field is the distance between the nearest and farthest objects that are in an acceptable sharp focus in an image. Objects behind and in front of the focus point are blurred.

The area in focus is called the focal point. It can be set by a value, or by choosing an object, and using the distance between the camera and the object.

## Focus on Object

Pick a focus object.

## Focus Distance

The distance to the focal point when no Focus Object is specified.

To display the distance by a yellow cross turn on Limits in the Viewport Display panel.

## Eyedropper Depth

Attention, crazy design! The Eyedropper Depth button is greyed out and remains not clickable, even when it highlights when you hover over the Focus Distance slider. It is just implemented to show the hotkey and how to call the eyedropper.

You can call a Depth picker by hovering with the mouse over the Focus Distance property and pressing hotkey E. Then click on a point in the 3D Viewport to sample the distance from that point to the camera.

## Aperture

### F-Stop

Defines the amount of blurring. Lower values give a strong depth of field effect.

### Blades

Total number of polygonal blades used to alter the shape of the blurred objects in the render, and render preview. As with the viewport, the minimum amount of blades to enable the bokeh effect is 3, resulting in a triangular-shaped blur.

### Rotation

Rotate the polygonal blades along the facing axis, and will rotate in a clockwise, and counter-clockwise fashion.

### Ratio

Change the amount of distortion to simulate the anamorphic bokeh effect. A setting of 1.0 shows no distortion, where a number below 1.0 will cause a horizontal distortion, and a higher number will cause a vertical distortion.

# Camera panel

## Presets

Camera presets. To add a new preset enter a name and click the + button. To

remove a preset click at the minus button besides the name.

**Note:** To adjust camera resolution and pixel aspect ratio, go to the Output Tab in the Format Panel, since the final resolution and aspect ratio is defined by the file format output.

## Sensor Fit

A method to fit the image aspect ratio and resolution with relative field of view angle inside the sensor dimensions.

### Auto

Adjust the relative focal length to the sensor width or height and adjust the image with a fixed aspect ratio to the image resolution from the Output Tab.

### Size

The sensor size according to the image resolution and pixel aspect ratio. This contains the automatic horizontal size of the image sensor area in millimeters.

### Horizontal

Adjust the relative focal length to the sensor width and adjust the image with a fixed aspect ratio to the image resolution from the Output Tab. Height cannot be modified.

### Width

The sensor width. This contains the horizontal size of the image sensor area.

### Vertical

Adjust the relative focal length to the sensor height and adjust the image with a fixed aspect ratio to the image resolution from the Output Tab. Width cannot be modified.

### Height

The sensor height. This contains the horizontal size of the image sensor area in millimeters.

## Save Areas panel

Modern LCD or plasma monitors usually doesn't have over scan areas anymore. But especially older TV screens still may have varying amounts of

over scan. And cuts quite a bit content away at the border. And so not all content is shown at all monitors. Safe areas is the area that is always visible at all hardware.

Safe areas are guides to ensure that the most important parts of the content can be seen across all screens. The lines are unfortunately a bit hard to see when you are in camera view. They mark the safe areas.

Safe areas can be set from the Camera and Sequencer views.

Tip! Each country sets a legal standard for broadcasting. These include also specific values for safe areas. Bforartists defaults for safe areas follow the EBU (European Union) standard. Make sure you are using the correct values when working for broadcast to avoid any trouble.

## Presets

Safe areas presets. To add a preset enter a name and click at the plus button. To remove a preset click at the minus button besides the preset name.

## Title Safe Margins X/Y

Also known as Graphics Safe. Information (graphics or text) inside this area can be seen by the majority of viewers.

## Action Safe Margins X/Y

An extra “margin” for the screen, which can be used to keep elements from piling up against the edges.

## Center-Cut Safe Areas

Center-cuts are a second set of safe areas to ensure content is seen correctly on screens with a different aspect ratio. Old TV sets receiving 16:9 or 21:9 video will cut off the sides. Position content inside the center-cut areas to make sure the most important elements of your composition can still be visible in these screens.

## Center Title Safe Margins X/Y

Information (graphics or text) inside this area can be seen by the majority of viewers.

## Center Action Safe Margins X/Y

An extra “margin” for the screen, which can be used to keep elements from piling up against the edges.

## Background Images panel

Add a background image or movie to the camera.

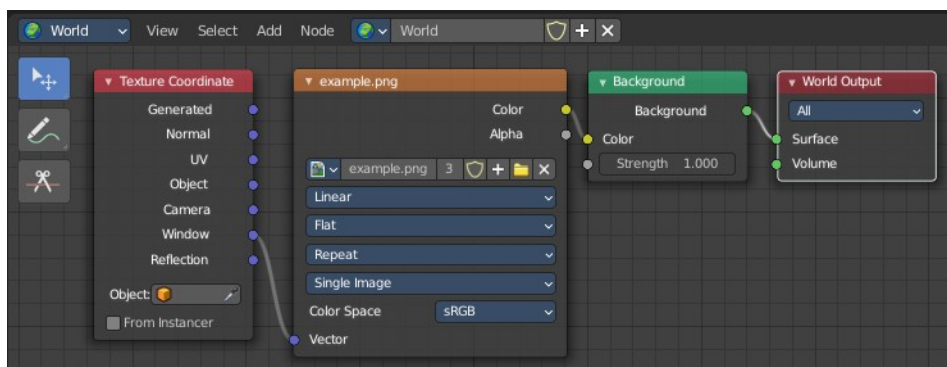

You can add more than one image or movie. The content can be offset and the opacity can be changed.

Note that an image that is added here does not render. It just displays in the viewport background.

To render the background image too you need to add it in a compositing step. Or in the Shading tab add the image in the World shader. Use Window as the mapping vector.

## Background Images panel

### Header

### *Background Images checkbox*

Activate or deactivate the background images.

### *Add Image*

Adds a new Image box. As told above, you can work with more than one image or movie clip. The image box can be removed by the X button at the left.

## Background Image box

### *Triangle Button*

You can collapse the background images box with the triangle button at the left.

### **Image / Movie name**

The name of the loaded movie or image. When there is no image loaded then the text is Not Set.

### **Show Background Image**

Display the image in the viewport when you are in camera view.

## Remove Background Image

Remove the background image.

---

## Background Source

What type to display. Image or Movie.

## Background Source Image

### *Image Property*

### Image Browser

Browse the available images or movie clips.

### *Image name*

The name of the image or movie clips.

### *Number of Users*

The number of users for this image.

### *Fake User*

Keep this image in the scene even if it has no users.

### *Open Image*

Opens a file browser where you can load an image.

### *Remove*

Removes this image as the active image. Note that the image is still available in the image browser.

---

## Source Type Single Image (Background source type image)

### Path edit box

### Pack

With this button you can pack the movie or the image sequence into the blend file. It gets packed when you save the blend file the next time.

### Path edit box

See and edit the path to your movie or image sequence files.

### Open

Open a new movie or image sequence files. A file dialog will appear.

### Refresh

Reread the movie or image sequence files.

---

## **Source Type Movie + Image Sequence (Background source type image)**

Attention. This is with Image as the background source. Background Source Movie Clip offers other options.

### **Path edit box**

#### **Pack**

With this button you can pack the movie or the image sequence into the blend file. It gets packed when you save the blend file the next time.

#### **Path edit box**

See and edit the path to your movie or image sequence files.

#### **Open**

Open a new movie or image sequence files. A file dialog will appear.

#### **Refresh**

Reread the movie or image sequence files.

### **Frames**

The number of frames of the movie or image sequence.

### **Start**

The start frame of the movie or image sequence

### **Offset**

Offset the number of the frame to use in the animation. -1 means off.

### **Cyclic**

Cycle the images in the movie.

### **Auto Refresh**

Always refresh image on frame changes.

## **Source Type Generated**

### **X / Y**

The image width and height.

## Float Buffer

Use a floating point buffer. 8 Bit images uses integers. 32 Bit works with floats.

---

### Generated Type Blank

This type displays an image with one blank color

#### Color

The color of the blank image.

### Generated Type UV Grid

This type displays a with a black and white checker texture but colored dots.

### Generated Type Color Grid

This type displays a with a colored checker texture with numbers.

## Source Type UDIM Tile

UDIM tiles is a way to deal with several textures in different resolution as one texture. Other software like Substance Painter also works with UDIM textures.

Note that you need to have a fitting numbers of UDIM tiles in the UDIM tiles panel. Or not all UDIM textures will be loaded. Which is impossible to set up from here. UDIM setup happens in UV Editor in Edit mode. It will just load the first tile of the Udim texture.

## Path edit box

### Pack

With this button you can pack the movie or the image sequence into the blend file. It gets packed when you save the blend file the next time.

### Path edit box

See and edit the path to your movie or image sequence files.

### Open

Open a new movie or image sequence files. A file dialog will appear.

### Refresh

Reread the file.

## Movie

### Active Clip

Use the movie clip from the active camera instead of a loaded one.

### File Path

#### Path edit box

See and edit the path to your movie or image sequence files.

### Open

Open a new movie or image sequence files. A file dialog will appear.

### Refresh

Reread the movie or image sequence files.

### Render Undistorted

Render Preview using undistorted proxy material.

### Proxy Size

This setting defines which proxy image resolution is used for display in the viewport. If there is no generated proxies, then the render size is set to "No proxy, full render"

## Color Space

Choose the color space type for the movie or image sequence files.

## Opacity

The transparency of the background image or movie.

## Depth

Choose whether the image is shown behind all objects, or in front of everything.

## Frame Method

Controls how the image is placed in the camera view.

## Stretch

Forces the image dimensions to match the camera bounds (may alter the aspect ratio).

## Offset X/Y

Positions the background image using these offsets.

In orthographic views the values are measured in the normal scene units. In the camera view the values are measured relative to the camera bounds (0.1 will offset it by 10% of the view width/height).

### **Rotation**

Rotates the image around its center.

### **Scale**

Scales the image up or down from its center.

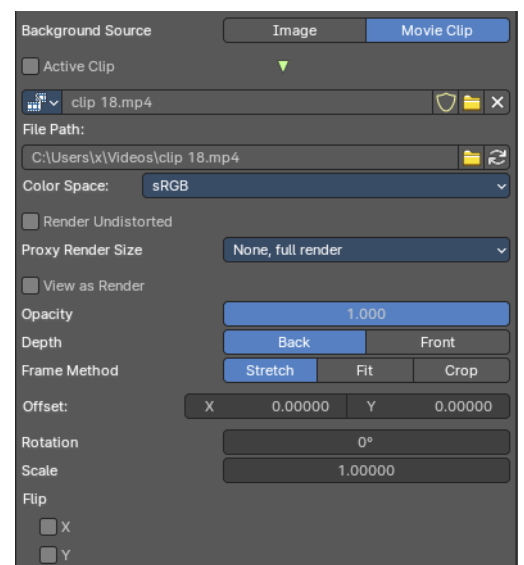

### **Flip X**

Swaps the image around, such that the left side is now on the right, and the right now on the left.

### **Y**

Swaps the image around, such that the top side is now on the bottom, and the bottom now on the top.

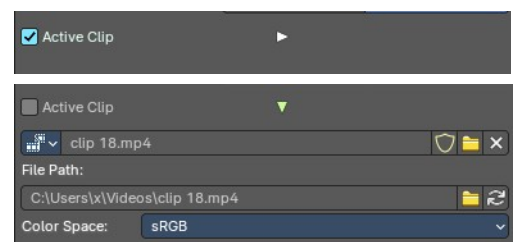

## **Background Source Movie**

### **Active Clip**

Use the active clip from the active camera instead of the loaded clip.

This includes also the color space settings.

### **Clip Property**

### **Clip Browser**

Browse the available images or movie clips.

### **Clip name**

The name of the image or movie clips.

### **Number of Users**

The number of users for this image.

### **Fake User**

Keep this image in the scene even if it has no users.

### **Open Image**

Opens a file browser where you can load an image.

### **Remove**

Removes this image as the active image. Note that the image is still available in the image browser.

### **File Path**

#### **Pack**

With this button you can pack the movie or the image sequence into the blend file. It gets packed when you save the blend file the next time.

#### **Path edit box**

See and edit the path to your movie or image sequence files.

#### **Open**

Open a new movie or image sequence files. A file dialog will appear.

#### **Refresh**

Reread the movie or image sequence files.

### **Color Space**

Choose the color space type for the movie or image sequence files.

### **Render Undistorted**

Render Preview using Undistorted Proxy.

### **Proxy Render Size**

Display the preview in full size, or with proxies in reduced size.

## ***View as Render***

Apply render part of display transformation when displaying this image on the screen.

## ***Opacity***

The transparency of the background image or movie.

## ***Depth***

Choose whether the image is shown behind all objects, or in front of everything.

## ***Frame Method***

Controls how the image is placed in the camera view.

## ***Stretch***

Forces the image dimensions to match the camera bounds (may alter the aspect ratio).

## ***Offset X/Y***

Positions the background image using these offsets.

In orthographic views the values are measured in the normal scene units. In the camera view the values are measured relative to the camera bounds (0.1 will offset it by 10% of the view width/height).

## ***Rotation***

Rotates the image around its center.

## ***Scale***

Scales the image up or down from its center.

## ***Flip X***

Swaps the image around, such that the left side is now on the right, and the right now on the left.

## ***Y***

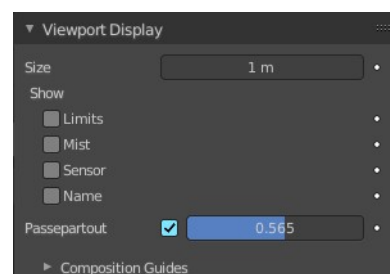

Swaps the image around, such that the top side is now on the bottom, and the bottom now on the top.

# Viewport Display panel

Viewport display settings.

## **Size**

Size of the camera visualization in the 3D Viewport. This setting has no effect on the render output of a camera.

## **Show**

### **Limits**

Shows a line which indicates Start and End Clipping

values. Displays also the depth of field focus point.

## Mist

Toggles viewing of the mist limits on and off. The limits are shown as two connected white dots on the camera line of sight. The mist limits and other options are set in the World panel, in the Mist section.

To activate the Mist panel you first have to activate the Mist pass in the View layer properties.

## Sensor

Displays a dotted frame for the sensor size (film gate) in the camera view.

The sensor size can be adjusted in the camera panel. It is fixed for the method Auto.

## Name

Display the name of the camera down left in the passepoutout.

## Passepartout

This option darkens the area outside of the camera's field of view.

## Alpha

Controls the transparency of the passepoutout mask.

## Composition Guides

Composition Guides enable overlays onto the camera display that can help when framing a shot.

## Thirds

Adds lines dividing the frame in thirds vertically and horizontally.

### **Center**

Adds lines dividing the frame in half vertically and horizontally.

### **Center**

### **Diagonal**

Adds lines connecting opposite corners.

### **Golden**

#### **Ratio**

Divides the width and height into Golden proportions (about 0.618 of the size from all sides of the frame).

### **Triangle A**

Displays a diagonal line from the lower left to upper right corners, then adds perpendicular lines that pass through the top left and bottom right corners.

### **Triangle B**

Same as A, but with the opposite corners.

### **Harmonious**

#### **Triangle A**

Displays a diagonal line from the lower left to upper right corners, then lines from the top left and bottom right corners to 0.618 the lengths of the opposite side.

#### **Triangle B**

Same as A, but with the opposite corners.

## Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

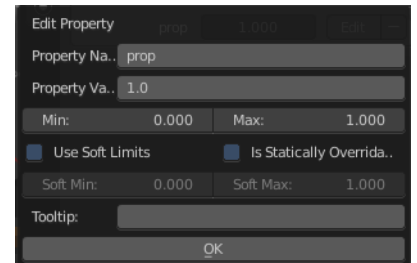

### Add

Adds a new property.

### Edit

Opens a panel where you can adjust the settings for the custom property.

### Remove

Removes the property.

## Preview panel

Provides a preview window for the light.

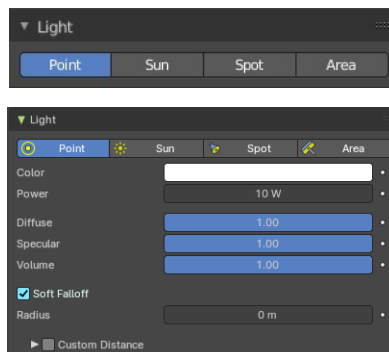

## Light panel

The light panel contains the settings for the different light types. Color, strength, and so on.

The content differs, depend and of the chosen renderer. Workbench has no settings here. So we just cover the panel content with Eevee and Cycles.

Some props can be animated by setting a keyframe with the Animate Property button behind.

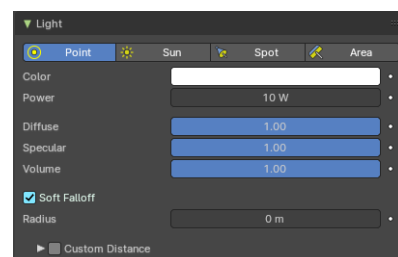

### Point Light Eevee

The light emits from a point, and has falloff.

#### Color

The color of the light. Clicking at the color field will open a color picker.

## Power

Power of the light in Watts. Higher values increase the intensity of the light. Negative values can be set, but should be avoided for predictable and physically based result.

## Diffuse

Diffuse Reflection multiplier.

## Specular

Specular Light intensity multiplier.

## Volume

Volume Light multiplier.

## Soft Falloff

Apply falloff to avoid sharp edges when the light geometry intersects with other objects.

## Radius

When larger than zero, light will be emitted from a spherical surfaces with the specified radius. Lights with larger size have softer shadows and specular highlights.

## Custom Distance

Eevee Renderer. If enabled uses Distance as the custom attenuation distance instead of global light threshold. In order to avoid long setup times, this distance is first computed automatically based on a light threshold. The distance is computed at the light origin and using the inverse square falloff.

## Distance

The distance where light influence will be set to 0.

## Point Light Eevee Next

The light emits from a point, and has falloff.

### Color

The color of the light. Clicking at the color field will open a color picker.

### Power

Power of the light in Watts. Higher values increase the intensity of the light. Negative values can be set, but should be avoided for predictable and physically based result.

## Diffuse

Diffuse Reflection multiplier.

## Specular

Specular Light intensity multiplier.

## Volume

Volume Light multiplier.

## Soft Falloff

Apply falloff to avoid sharp edges when the light geometry intersects with other objects.

## Radius

When larger than zero, light will be emitted from a spherical surfaces with the specified radius. Lights with larger size have softer shadows and specular highlights.

## Cast Shadow

Light source casts shadow.

## Shadow Softness

Scale light shape for softer shadows.

## Filtering Radius

Blur shadow aliasing.

## Custom Distance

Eevee Renderer. If enabled uses Distance as the custom attenuation distance instead of global light threshold. In order to avoid long setup times, this distance is first computed automatically based on a light threshold. The distance is computed at the light origin and using the inverse square falloff.

## Distance

The distance where light influence will be set to 0.

## Point Light Cycles

The light emits from a point, and has falloff.

## Color

The color of the light. Clicking at the color field will open a color picker.

## Power

Power of the light in Watts. Higher values increase the intensity of the light. Negative values can be set, but should be avoided for predictable and physically based result.

## Soft Falloff

Apply falloff to avoid sharp edges when the light geometry intersects with other objects.

## Radius

When larger than zero, light will be emitted from a spherical surfaces with the specified radius. Lights with larger size have softer shadows and specular highlights.

## Max Bounces

Cycles renderer. Maximum number of times light from the light is allowed to bounce. Limited by scene-wide bounce settings.

## Cast Shadow

Light casts shadow.

## Multiple Importance

Multiple importance sampling reduces noise for area lights and sharp glossy materials.

---

## Sun Light Eevee

The light has no falloff, and goes into one direction.

### Color

The color of the light. Clicking at the color field will open a color picker.

### Strength

Strength of the light in Watts per square meter.

### Diffuse

Diffuse Reflection multiplier.

### Specular

Specular Light intensity multiplier.

### Volume

Volume Light multiplier.

## Angle

The size of the sun light according to its angular diameter as seen from earth.

---

## Sun Light Eevee Next

The light has no falloff, and goes into one direction.

### Color

The color of the light. Clicking at the color field will open a color picker.

### Strength

Strength of the light in Watts per square meter.

### Diffuse

Diffuse Reflection multiplier.

### Specular

Specular Light intensity multiplier.

### Volume

Volume Light multiplier.

### Angle

The size of the sun light according to its angular diameter as seen from earth.

### Cast Shadow

Light source casts shadow.

### Shadow Softness

Scale light shape for softer shadows.

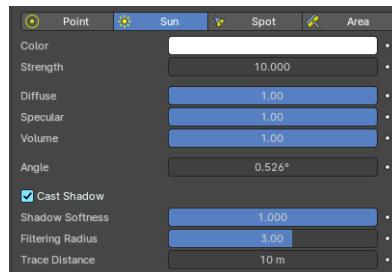

### Filtering Radius

Blur shadow aliasing.

### Trace Distance

The maximum distance a shadow ray can travel.

---

## Sun Light Cycles

The light has no falloff, and goes into one direction.

## Color

The color of the light. Clicking at the color field will open a color picker.

## Strength

Strength of the light in Watts per square meter.

## Angle

The size of the sun light according to its angular diameter as seen from earth.

## Max Bounces

Cycles renderer. Maximum number of times light from the light is allowed to bounce. Limited by scene-wide bounce settings.

## Cast Shadow

Light casts shadow.

## Multiple Importance

Multiple importance sampling reduces noise for area lights and sharp glossy materials.

## Shadow Caustics

Generate apporximate caustics in shadows of refractive surfaces. Lights, Caster and receiver objects must have shadow caustics option set to enabled to get this to work.

---

## Spot Light Eevee

The light has falloff. And gets distributed in a cone shape.

### Color

The color of the light. Clicking at the color field will open a color picker.

### Power

Strength of the light in Watts per square meter.

### Diffuse

Diffuse Reflection multiplier.

### Specular

Specular Light intensity multiplier.

### Volume

Volume Light multiplier.

## Soft Falloff

Apply falloff to avoid sharp edges when the light geometry intersects with other objects.

## Radius

When larger than zero, light will be emitted from a spherical surfaces with the specified radius. Lights with larger size have softer shadows and specular highlights.

## Custom Distance

Eevee Renderer. If enabled uses Distance as the custom attenuation distance instead of global light threshold. In order to avoid long setup times, this distance is first computed automatically based on a light threshold. The distance is computed at the light origin and using the inverse square falloff.

## Distance

The distance where light influence will be set to 0.

## Spot shape

Eevee renderer.

## Size

The size of the outer cone of a spot.

## Blend

Blending to the inner cone of a spot. The inner cone boundary line indicates the point at which light from the Spot will start to blur/soften.

## Show cone

Shows the cone opaque in the 3D view

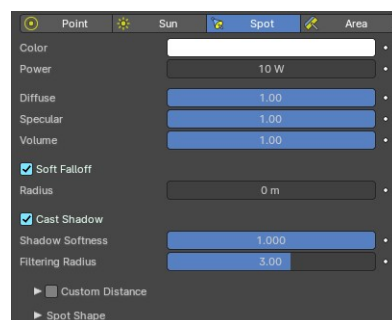

## Spot Light Eevee Next

The light has falloff. And gets distributed in a cone shape.

## Color

The color of the light. Clicking at the color field will open a color picker.

## Power

Strength of the light in Watts per square meter.

## Diffuse

Diffuse Reflection multiplier.

## Specular

Specular Light intensity multiplier.

## Volume

Volume Light multiplier.

## Soft Falloff

Apply falloff to avoid sharp edges when the light geometry intersects with other objects.

## Radius

When larger than zero, light will be emitted from a spherical surfaces with the specified radius. Lights with larger size have softer shadows and specular highlights.

## Cast Shadow

Light source casts shadow.

## Shadow Softness

Scale light shape for softer shadows.

## Filtering Radius

Blur shadow aliasing.

## Custom Distance

Eevee Renderer. If enabled uses Distance as the custom attenuation distance instead of global light threshold. In order to avoid long setup times, this distance is first computed automatically based on a light threshold. The distance is computed at the light origin and using the inverse square falloff.

## Distance

The distance where light influence will be set to 0.

## Spot shape

Eevee renderer.

## Size

The size of the outer cone of a spot.

## Blend

Blending to the inner cone of a spot. The inner cone boundary line indicates the point at which light from the Spot will start to blur/soften.

## Show cone

Shows the cone opaque in the 3D view

## Spot Light Cycles

The light has falloff. And gets distributed in a cone shape.

## Color

The color of the light. Clicking at the color field will open a color picker.

## Power

Strength of the light in Watts per square meter.

## Soft Falloff

Apply falloff to avoid sharp edges when the light geometry intersects with other objects.

## Radius

When larger than zero, light will be emitted from a spherical surfaces with the specified radius. Lights with larger size have softer shadows and specular highlights.

## Max Bounces

Maximum number of times light from the light is allowed to bounce. Limited by scene-wide bounce settings.

## Cast Shadow

Light casts shadow.

## Multiple Importance

Multiple importance sampling reduces noise for area lights and sharp glossy materials.

## Beam shape

Eevee renderer.

## Size

The size of the outer cone of a spot.

## Blend

Blending to the inner cone of a spot. The inner cone boundary line indicates the point at which light from the Spot will start to blur/soften.

## Show cone

Shows the cone opaque in the 3D view

## Shadow Caustics

Generate approximate caustics in shadows of refractive surfaces. Lights, Caster and receiver objects must have shadow caustics option set to enabled to get this to work.

## Area Light Eevee

The light emits from a surface, and has falloff.

### Color

The color of the light. Clicking at the color field will open a color picker.

### Power

Power of the light in Watts. Higher values increase the intensity of the light.

Negative values can be set, but should be avoided for predictable and physically based result.

### Diffuse

Diffuse Reflection multiplier.

### Specular

Specular Light intensity multiplier.

### Volume

Volume Light multiplier.

### Shape

The shape of the light emitting surface.

### Size

The size of the light emitting surface.

## Custom Distance

Eevee Renderer. If enabled uses Distance as the custom attenuation distance instead of global light threshold. In order to avoid long setup times, this distance is first computed automatically based on a light threshold. The distance is computed at the light origin and using the inverse square falloff.

## Distance

The distance where light influence will be set to 0.

## Area Light Eevee Next

The light emits from a surface, and has falloff.

### Color

The color of the light. Clicking at the color field will open a color picker.

### Power

Power of the light in Watts. Higher values increase the intensity of the light. Negative values can be set, but should be avoided for predictable and physically based result.

### Diffuse

Diffuse Reflection multiplier.

### Specular

Specular Light intensity multiplier.

### Volume

Volume Light multiplier.

### Shape

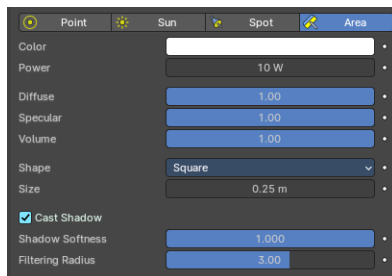

The shape of the light emitting surface.

### Size

The size of the light emitting surface.

### Cast Shadow

Light source casts shadow.

## Shadow Softness

Scale light shape for softer shadows.

## Filtering Radius

Blur shadow aliasing.

## Custom Distance

Eevee Renderer. If enabled uses Distance as the custom attenuation distance instead of global light threshold. In order to avoid long setup times, this distance is first computed automatically based on a light threshold. The distance is computed at the light origin and using the inverse square falloff.

## Distance

The distance where light influence will be set to 0.

## Area Light Cycles

The light emits from a surface, and has falloff.

## Color

The color of the light. Clicking at the color field will open a color picker.

## Power

Power of the light in Watts. Higher values increase the intensity of the light. Negative values can be set, but should be avoided for predictable and physically based result.

## Shape

The shape of the light emitting surface.

## Size

The size of the light emitting surface.

## Max Bounces

Cycles render. Maximum number of times light from the light is allowed to bounce. Limited by scene-wide bounce settings.

## Custom Distance

Eevee Renderer. If enabled uses Distance as the custom attenuation distance instead of global light threshold. In order to avoid long setup times, this distance is first computed automatically based on a light threshold. The distance is computed at the light origin and using the inverse square falloff.

## ***Distance***

The distance where light influence will be set to 0.

## **Cast Shadow**

Cycles renderer. The light source casts a shadow.

## **Multiple Importance**

Cycles renderer. By default lights use only direct light sampling. Which can be noisy with sharp glossy reflections. Multiple Importance activates Indirect light sampling to reduce noise.

## **Shadow Caustics**

Generate approximate caustics in shadows of refractive surfaces. Lights, Caster and receiver objects must have shadow caustics option set to enabled to get this to work.

---

## **Portal**

With Cycles Area lights can also function as light portals to help sample the environment light. This can significantly reduce noise in interior scenes. Light portals are not helpful for outdoor scenes. Since outdoor the light bounces just fly off into the sky.

Using the light as portal hides it.

## **Beam Shape Subpanel**

### ***Spread***

How widely the emitted light fans out.

## **Shadow panel**

Eevee renderer shadow settings. Eevee is a realtime renderer. And in Eevee shadows are done with shadow maps.

### **Clip Start**

Shadow clip start distance. A distance below will not generate a shadow.

### **Bias**

The bias to reduce self shadowing.

## **Cascaded Shadow Map**

Sun light only. Shadow large scenes by distributing multiple shadow maps over the frustum range. Each

cascade covers a different portion of the view frustum. Note that cascade shadow maps are always updated because they are view dependent.

Note! In orthographic view the cascades cover the whole depth range of the camera with an evenly distributed shadow precision.

## Count

Number of cascades to use. More cascades means better precision but a lower update rate.

## Fade

Fade transition area between two cascades. Higher values means less overall resolution because cascades need to overlap.

## Max Distance

Distance away from the view origin (or camera origin if in camera view) to cover by the cascade. If the view far clip distance is lower than Max Distance, the view far clip distance will be used. Only works in perspective view.

## Distribution

Puts more resolution towards the near clip plane. Only works in perspective view.

## Contact Shadows

Contact shadows exists to fix light leaking caused by bias or shadow map undersampling. The same limitations applies like for screen space reflections. Unknown object thickness and effect disappearing at screen edges.

Tip! Keep the distance of contact shadows small. They are not accurate enough to shadow the entire scene.

## Distance

World space distance in which to search for screen space occluder.

## Bias

Bias applied to the ray tracing to reduce self-shadowing artifacts.

## Thickness

Pixel thickness used to detect occlusion, treating any potential occluder as this thick.

## Light panel - Spot Shape subpanel

### Size

The size of the outer cone of a spot.

## Blend

Blending to the inner cone of a spot. The inner cone boundary line indicates the point at which light from the Spot will start to blur/soften.

## Show cone

Shows the cone opaque in the 3D view.

## Nodes panel

### Use Nodes

Use nodes for the light setup. Creates the standard nodes for an emission light. Which can be found in the Node editor then. Once activated the Nodes panel shows the content of the emission node.

To revert, and not to use nodes, untick the Use Nodes checkbox in the node editor.

## Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

### Add

Adds a new property.

## Edit

Opens a panel where you can adjust the settings for the custom property.

## Remove

Removes the property.

## Light Probes Introduction

Light Probe objects are just useful for Eevee and Cycles. Working with Light probes is a real time render technique. The light gets precalculated into a light probe object that are then used to indirectly light the scene.

There are three different probe types: Sphere/Box, Plane and Volume. Volume and Plane is meant for specular lighting. Sphere/Box is used for diffuse lighting.

## General Use

Add the Light Probe to the scene, use them in strategic positions covering the scene objects, and adjust settings.

To work with the Volume light probes you need to bake them.

## Sphere

Adds a reflective light probe in sphere shape. A light probe sphere records the light incoming from many directions at a single location.

### Use

Used for smooth and semi-rough reflections. Sphere probes smoothly blend to light probe volume lighting for completely diffuse reflections.

**Note:** *If Raytracing is turned on, they are used as a fallback if a ray misses.*

## Plane

Adds a reflective light probe in plane shape. A light probe plane records the light incoming from a single direction for all visible points on a plane.

### Use

Light probe planes only work when the ray tracing method is set to screen-tracing in the Render Properties tab of the Prop. When enabled, they accelerate the tracing process and complete the missing data from the screen space ray tracing.

**Note:** *The specular reflection direction is the only one currently available. This type of light probe is suited to smooth planar surfaces. Each visible planar light probe increases the render time as the scene needs to be rendered for each of them.*

## Volume

Adds a volumetric array light probe in a bounding box.

### Use

A volume probe records the light incoming from all directions at many locations inside a volume. The capture point positions are visible as an overlay with dots in a 3D grid when the Irradiance Volume object is selected and affects any object inside the volume 3D Grid.

**Note:** *Light is filtered and only the diffuse light is recorded. If an object is not inside any Irradiance Volume, or if the indirect lighting has not been baked, the world's diffuse lighting will be used to shade it.*

## Probe panel

### Sphere

The Shere probe is useful

### Type

The type of the influence volume. It can either sample a sphere or a bounding box.

### Radius

A probe object only influences the lighting of nearby surfaces. This influence zone is defined by the Distance parameter and object scaling. The influence distance varies a bit, depending on the probe type.

For Reflection Cubemaps the influence volume can either be a box or a sphere centered on the probe's origin.

### Falloff

Percentage of the influence distance during which the influence of a probe fades linearly.

### Clipping Start/End

**Note:** *Cycles only*

Define the near and far clip distances when capturing the scene.

### Visibility

#### Visibility Collection

**Note:** *Cycles only*

In some cases, it is useful to limit which objects appear in the light probe's captured lighting. For instance, an object that is too close to a capture point might be better excluded. This is what the visibility collection does. Only objects that are in this collection will be visible when this probe will capture the scene.

There is also an option to invert this behavior and effectively hide the objects inside this collection.

**Note:** *This is only a filtering option. That means that if an object is not visible at render time it won't be visible during the probe render.*

**Note:** *Due to a limitation, dupli-objects cannot be hidden by using this option.*

## Plane

### Distance

A probe object only influences the lighting of nearby surfaces. This influence zone is defined by the Distance parameter and object scaling. The influence distance varies a bit, depending on the probe type.

For Reflection Planes the influence distance is the distance from the plane. Only surfaces whose normals are aligned with the Reflection Plane will receive the captured reflection.

### Clipping Offset

**Note:** *Cycles only*

Define how far below the plane the near clip is when capturing the scene.

**Note:** *Increasing this can fix reflection contact problems.*

### Visibility

**Note:** *This group of properties is Cycles only*

#### **Bias (Deprecated)**

Bias for reducing self shadowing.

#### **Bleed Bias (Deprecated)**

Bias for reducing light-bleed on variance shadow maps.

#### **Blur (Deprecated)**

Filter size of the visibility blur.

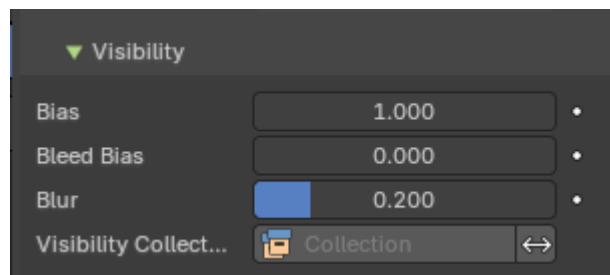

#### **Visibility Collection**

In some cases, it is useful to limit which objects appear in the light probe's captured lighting. For instance, an object that is too close to a capture point might be better excluded. This is what the visibility collection does. Only objects that are in this collection will be visible when this probe will capture the scene.

There is also an option to invert this behavior and effectively hide the objects inside this collection.

**Note:** *This is only a filtering option. That means that if an object is not visible at render time it won't be visible during the probe render.*

**Note:** *Due to a limitation, dupli-objects cannot be hidden by using this option.*

## Volume

### Intensity

Intensity factor of the recorded lighting from the light probe. Adjusting this parameter to anything other than 1.0 is not physically correct. Use this for tweaking, animating or artistic purposes.

### Normal Bias

Offset sampling of the irradiance grid in the surface normal direction to reduce light bleeding.

**Note:** *Can lead to specular highlight artifacts appearing if diffuse surface is set too high.*

### View Bias

Offset sampling of the irradiance grid in the viewing direction to reduce light bleeding.

**Note:** *Can lead to view dependent results if set too high. Adjust this if camera is static in animations.*

### Facing Bias

When set to zero, this helps avoid capturing points behind the shaded surface that may bleed light onto the shaded surface.

**Note:** *This produces non-smooth interpolation when the capture resolution is high. Increasing this bias will make the interpolation smoother but also introduce some light bleeding.*

### Validity Threshold

During the baking process, a validity score is assigned to each capture point. Capture points with validity below this threshold will be ignored during lighting interpolation. This remove the influence of capture points trapped inside closed geometry, reducing the artifacts they produced.

**Note:** *During the baking process, a validity score is assigned to each capture point. This score is based on the number of back-faces hit when capturing the incoming lighting. Only materials with Single Sided turned on for Light Probe Volumes will reduce the validity score.*

### Dilation Threshold

During the baking process, a validity score is assigned to each capture point. Capture points with validity below this threshold will have their data replaced using valid neighbors.

### Radius

Radius in capture points in which to search for a valid neighbor.

## Visibility

### Visibility Collection

**Note:** *Cycles only*

In some cases, it is useful to limit which objects appear in the light probe's captured lighting. For instance, an object that is too close to a capture point might be better excluded. This is what the visibility collection does. Only objects that are in this collection will be visible when this probe will capture the scene.

There is also an option to invert this behavior and effectively hide the objects inside this collection.

**Note:** *This is only a filtering option. That means that if an object is not visible at render time it won't be visible during the probe render.*

**Note:** *Due to a limitation, dupli-objects cannot be hidden by using this option.*

## Capture panel

**Note:** *The Capture panel is Eevee only.*

### Clipping Start / End

**Note:** *Sphere Light Probe only.*

Define the near and far clip distances when capturing the scene.

### Clipping Offset

**Note:** *Plane Light Probe only.*

Define how much below the plane the near clip is when capturing the scene. Increasing this can fix reflection contact problems.

## Custom Parallax panel

**Note:** *Sphere Light Probe only.*

By default, the influence volume of a Sphere and Box light probe is also the parallax volume. The parallax volume is a volume where the recorded lighting is projected. It should roughly fit surrounding area the light probe should influence. In some cases it may be better to adjust the parallax volume without touching the influence parameters. In this case, enable the Custom Parallax and change the shape and distance of the parallax volume independently.

## Custom Parallax Toggle

Turn the custom parallax on/off.

## Type

The type of parallax volume. One is a sphere shape, the other is a box shape.

## Radius

The radius of the parallax volume. Measured by the lowest corner of the parallax bounding box.

## Bake panel

**Note:** *Volume Light Probe only.*

Light probe volume light data is static and needs to be manually baked. Once baked, the data is stored inside the object data-block and can be moved, animated and linked between blender files.

**Note:** *Baking uses the render visibility of the objects in the scene.*

## Bake Light Cache

Bakes the light cache to the scene data. This may take a moment.

## Delete Light Cache

Removed the light cache from the scene data.

## Resolution

### Resolution X, Y, Z

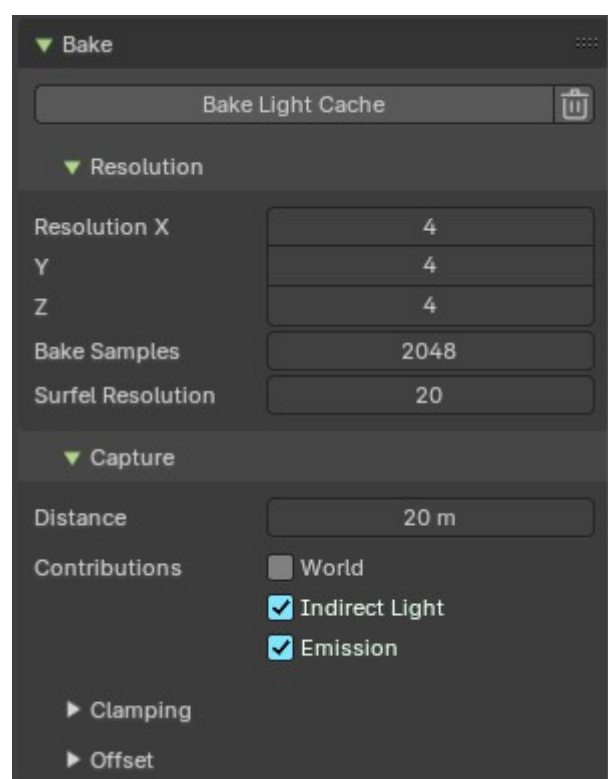

Spatial resolution for volumetric light probes is determined per probe. The local volume is divided into a regular grid of the specified dimensions. The lighting will be captured for each cell in this grid.

### Bake Samples

Number of ray directions to evaluate when baking. This increases the baking time proportionally to the size of the scene contents.

### Surfel Resolution

Number of surfels to spawn in one local unit distance. A serfel is similar to a lighting “voxel”. Higher values increase quality, but have a huge impact on memory usage. General recommendation is twice the value.

## Capture

### Capture Distance

Distance around the light probe volume that will be captured during the bake.

**Note:** A distance of 0 will only considered the inside of the volume.

### World Contribution

Bake incoming light from the world instead of just scene contents visibility for more accurate lighting, in exchange for less correct blending to surrounding irradiance volumes.

### Indirect Light Contribution

Capture light bounces from light source.

### Emission Contribution

Capture emissive surfaces when baking.

## Clamping

### Direct Light

Clamp incoming direct light. 0 disables direct light clamping.

**Note:** Here direct light refers to the light that bounces only once (from the light object) or light coming from emissive materials.

### Indirect Light

Clamp incoming indirect light. 0 disables indirect light clamping.

**Note:** Here indirect light refers to the light that bounces off a surface after the first bounce (from the light object) or during the first bounce if the light comes from emissive materials.

## Offset

In order to reduce artifacts caused by difficult capture point positioning, the bake process adjusts their location before capturing light. It moves the capture points slightly away from surrounding surfaces and tries to move them out of objects if they are not too far below the surface.

## Surface Offset

Distance to move the capture points away from surfaces.

## Search Distance

Distance to search for valid capture positions if the capture point is near the back-face of a single-sided object.

**Note:** Only materials with *Single Sided* turned on for *Light Probe Volumes* will move capture point position.

# Viewport Display panel

## Sphere

### Data

Show the captured light using small diffuse sphere of the given size.

### Influence

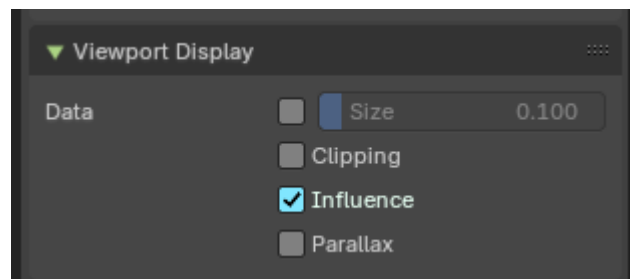

Show the influence bounds in the 3D Viewport. The inner sphere is where the falloff starts.

### Clipping

Show the clipping distance in the 3D Viewport.

### Parallax

Show the Custom Parallax shape in the 3D Viewport.

## Plane

### Arrow Size

Size of the arrow showing the reflection plane normal.

### Capture

Show the captured reflected image onto a fully reflective plane in the 3D Viewport.

### Influence

Show the influence bounds in the 3D Viewport.

## Volume

### Data

Show the captured light using small diffuse sphere of the given size.

### Clipping

Show the clipping distance in the 3D Viewport.

### Influence

Show the influence bounds in the 3D Viewport. The inner sphere is where the falloff starts.

## Custom Properties Panel

**Note:** *This is Cycles only.*

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

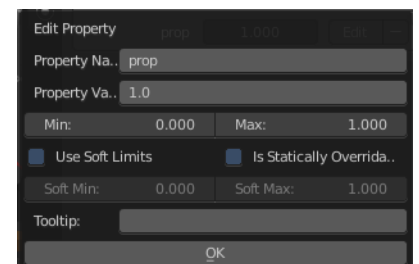

### Add

Adds a new property.

### Edit

Opens a panel where you can adjust the settings for the custom property.

### Remove

Removes the property.

## Force field of type Curve Guide

The curve guide is a curve style object. And so it has the same settings and panels than a curve object.

To keep the redundancies in the manual at a minimum, please have a look at the chapter for the object data properties for a curve object.

### 25.12.2 Editors - Properties Editor - Object Data Tab - Curve Object

## Empty panel

Most of the force field types are displayed as an empty. And so you will see the same empty display settings as for a regular empty.

Empties are objects without additional geometry. They do not render. A use case is that you use empties as handlers for a rigged character.

### Display As

Empties have graphical elements to display the location. In this drop down list you can choose the shape of this graphical element.

Further display settings can be found in the Object Properties tab in the Viewport Display panel.

### Size

The size of the graphical element.

### Image

Empties can display images. This images can be used to create reference images to model along. The image is always displayed, independent of the 3D

display mode.

### ***Offset X, Y***

Offset the image origin. 1.0 represents the width/height of the image.

### ***Depth***

#### **Default**

Use normal depth behavior.

#### **Front**

Always display on top of other objects.

#### **Back**

Always display behind of other objects.

#### ***Side***

#### **Both**

Display both the front and back of the empty.

#### **Front**

Only display the front of the image.

#### **Back**

Only display the back of the image.

### ***Show in***

#### **Orthographic**

Show in orthographic view.

#### **Perspective**

Show in perspective view.

#### **Only Axis Aligned**

Only displays the image contents when the view is aligned with the object's local axis.

### ***Transparency***

Use alpha blending instead of alpha-test. The image then blends with the background but can have depth sorting artifacts.

#### **Opacity**

The opacity.

## Image panel

When you choose an empty of type Image then this panel with further settings appears.

## Image property

### Image Browser

A list of available images in the scene.

### Open

When no image is loaded the open button is displayed. Open an image opens the file browser to load an image.

### Name

The name of the currently active image.

### Fake User

Keep this image in the scene even if it has no user.

### Open Image

Open image opens the file browser to load an image.

### Source

What image type to choose.

### Source Type Single Image

### Path edit box

### Pack

With this button you can pack the movie or the image sequence into the blend file. It gets packed when you save the blend file the next time.

### Path edit box

See and edit the path to your movie or image sequence files.

## Open

Open a new movie or image sequence files. A file dialog will appear.

## Refresh

Reread the movie or image sequence files.

## Color Space

Choose the color space type for the movie or image sequence files.

---

## Source Type Movie + Image Sequence

## Path edit box

## Pack

With this button you can pack the movie or the image sequence into the blend file. It gets packed when you save the blend file the next time.

## Path edit box

See and edit the path to your movie or image sequence files.

## Open

Open a new movie or image sequence files. A file dialog will appear.

## Refresh

Reread the movie or image sequence files.

---

## Info string

Some information about the currently loaded movie. Frames, resolution and color space.

---

## Frames

The number of frames of the movie or image sequence.

## Start

The start frame of the movie or image sequence

## Offset

Offset the number of the frame to use in the animation. -1 means off.

## Cyclic

Cycle the images in the movie.

## Auto Refresh

Always refresh image on frame changes.

---

## Color Space

Choose the color space type for the movie or image sequence files.

## Source Type Generated

### X / Y

The image width and height.

### Float Buffer

Use a floating point buffer. 8 Bit images uses integers. 32 Bit works with floats.

---

## Generated Type Blank

This type displays an image with one blank color.

## Color

The color of the blank image.

## Generated Type UV Grid

This type displays a with a black and white checker texture but colored dots.

## Generated Type Color Grid

This type displays a with a colored checker texture with numbers.

## Color Space

Choose the color space type for the image.

## Source Type Udim

UDIM is an enhancement to the UV mapping and texturing workflow. And does not belong here. But in the UV Editor. It is just in the list because it shares the same menus with the UV Editor.

You can load a UDIM file. But it will just display the first tile of the UDIM image. And there is no way to adjust the UDIM settings since they are in the UV Editor, in Edit mode. And Empties have no Edit mode.

# Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

## Add

Adds a new property.

## Edit

Opens a panel where you can adjust the settings for the custom property.

## Remove

Removes the property.

## 26.14.16 Editors - Properties Editor - Object Data Properties Tab - Point Cloud Object

## Point Cloud

Point clouds can represent 3D scans. It is also planned to represent particles in the future. Each point can store data in a set of Attributes. These attributes can be managed here.

## Attributes panel

The Attributes panel contains different point cloud characteristics such as the position and size of points. This data can then for example be used in the shader editor or in the compositor editor.

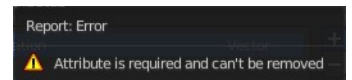

### List View

A list of the attributes.

## Position Attribute

The position of the point in 3D space. Type Vector. Not in the menu. This attribute exists from the beginning. And can't be added or removed.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## Add Attribute menu

### Radius

The radius of each point. Type Float.

### Color

The color of each point. Type Float Color.

### Particle ID

A unique identifier given to each particle. Type Integer.

### Velocity

The speed and direction that the particle is traveling. Type Vector.

### Custom

Custom attribute can be given to particles to hold a custom characteristic. Clicking this menu item will open a popup where you can adjust the custom properties.

### Name

The name of the attribute.

### Data Type

The type of data to store in the attribute.

### Float

Floating point value.

### Integer

32-bit integer.

### Vector

3D vector with floating point values.

## Float Color

RGBA color with floating point precision.

## Byte Color

RGBA color with 8-bit precision.

## String

Text string.

## Domain

The type of element the attribute is stored in. Currently, attributes can only be stored per Point.

## Remove Geometry Attribute

Remove the attribute from the list.

# Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

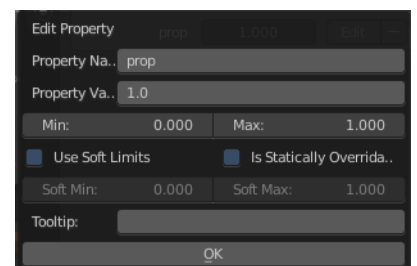

## Add

Adds a new property.

## Edit

Opens a panel where you can adjust the settings for the custom property.

## Remove

Removes the property.

## Vertex groups panel

A Vertex group is a group of vertices, a selection of the mesh. It is for example used to weight a specific mesh part to a bone. Or to control the growth of hair particles.

This panel allows you to manage and edit vertex groups. Weight painting creates vertex groups automatically.

In Edit mode this panel shows some further controls.

Vertex groups exists for mesh and lattice objects.

### Active Vertex Group list

A List of the vertex groups for this mesh.

#### Group name

The name of the group. It can be renamed by double clicking at it.

#### Lock

The lock icon at the end of a group name locks the group from being editable.

#### Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

#### Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## ***Invert***

Exclude the search term instead of searching for it.

## ***Sort by Name***

Sort the List by name.

## ***Add +***

Create an empty vertex group.

## ***Remove -***

Deletes the active vertex group.

## **Specials menu**

### **Sort by Name**

Sorts the vertex groups alphabetically by name.

### **Sort by Bone Hierarchy**

Sorts the vertex groups by the hierarchy of the assigned bones.

### **Copy Vertex Group**

Add a copy of the active vertex group as a new group. The new group will be named like the original group with “\_copy” appended at the end of its name. And it will contain associations to exactly the same vertices with the exact same weights as in the source vertex group.

### **Copy Vertex Groups to Linked**

Copy vertex groups of this mesh to all linked objects which use the same mesh data (all users of the data).

### **Copy Vertex Group to Selected**

Copy all vertex groups to other selected objects provided they have matching indices (typically this is true for copies of the mesh which are only deformed and not otherwise edited).

### **Mirror Vertex Group**

Mirrors weights and/or flips group names from one side of a symmetrical mesh to the other.

Only mirroring along local X axis is supported. Vertices that have no corresponding vertex on the other side will not be affected. Note, the weights are not transferred to the corresponding opposite bone weight group.

## Mirror Vertex Group (Topology)

Performs the Mirror Vertex Group with the Topology Mirror option enabled.

## Remove from All Groups

Unassigns the selected vertices from all groups. Even locked.

## Clear Active Group

Remove all assigned vertices from the active group. The group is made empty. Note that the vertices may still be assigned to other vertex groups of the object. This feature does not affect locked groups.

## Delete All Unlocked Groups

Remove all vertex groups from the object that are not locked.

## Delete All Groups

Remove all vertex groups from the object.

## Lock All

Lock all groups.

## Unlock All

Unlock all groups.

## Lock Invert All

Invert group locks.

## Move Vertex Group Up / Down

Moves the selected vertex group up or down in the list.

## Assign

Assign the selected vertices to the active vertex group.

## Remove

Remove the selected vertices from the active group.

## Select

Select all vertices in the group.

## Deselect

Deselect all vertices in the group.

## Weight

The weight value that gets assigned to the selected vertices.

## Set Active Group

Lets you select the group that will become the active one (menu only).

## Shape Keys panel

This panel allows you to see and manage shape keys. A shape key is a vertex animation.

Shape keys are for example used for facial animations, when you don't want to use a face rig with bones. The idea is to model a shape key pose for smiling, one for laughing, one for sad, and so on. And then blend the shape key poses together as needed.

Shape keys are also called morph targets or blend shapes.

## Workflow

In Object mode add a shape key. This first shape key is called Basis by default. It is the base for the vertex animation. This basis shape key is the base shape for all further shape keys. It cannot be modified or keyframed.

Now add a second shape key. This second shape key will have more controls so that you can modify it in the needed way.

Enter edit mode with this key 1 selected.

Modify the geometry by moving some vertices around.

Switch back to Object mode.

Have a look at the value slider. This slider defines how the key 1 shape key blends with the Basis shape key.

Move it from value 0 to value 1. You will notice that the vertices that you

have modified in Key 1 will now start to move to a new position. Dependent of how strong the value is. With a value of 1 it will be at the position of how you modeled it.

To keyframe this shape click at the Animate property dot behind the slider. The slider will change its color. And the dot will change to a rhombus shape to indicate that there is a keyframe recorded at this frame.

Or you right click at the slider, and choose Insert Keyframe in the menu.

Move to another frame. Change the slider value, and set another keyframe.

Recorded keyframes can be found and further tweaked in the Dope sheet Editor in Shape Key Editor mode. Here you can also record further keyframes under Key / Insert Keyframes. And control the slider values from the channel list.

Add more shape keys and model and animate them as you need them.

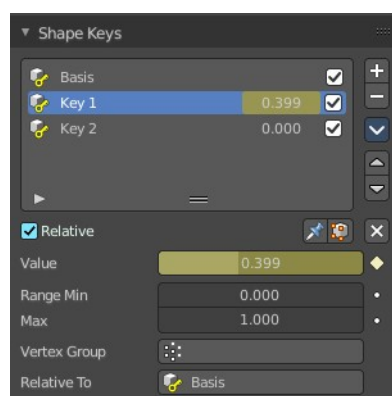

## Active Shape Key Index

A List of the shape keys for this mesh.

It contains two types of shape keys. Basis is the base shape. The other type relies at this shape as the base.

## Shape Key name

The name of the shape key. It can be renamed by double clicking at it.

## Slider value

The blend value of this shape key. The Basis shape key does not have such a slider.

## Lock

The lock icon at the end of a group name locks the group from being editable.

## Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## Invert

Exclude the search term instead of searching for it.

## **Sort by Name**

Sort the List by name.

## **Add +**

Create a shape key.

## **Remove -**

Delete the selected shape key.

## **Specials menu**

### **New Shape From Mix**

Add a new shape key with the current deformed shape of the object.

### **Mirror Shape Key**

Mirror the shape keys on the X axis. This will not work if the mesh vertices is not fully symmetrical.

### **Mirror Shape Key (Topology)**

Mirror the shape keys on the X axis. But detects the mirrored vertices based on the topology of the mesh. The mesh vertices do not have to be perfectly symmetrical for this action to work.

### **Join as Shapes (Transfer Mix)**

Transfer the current resulting shape from a different object.

Select the object to copy, hold down Shift, then the object to copy into. Use this action and a new shape key will be added to the active object with the current mix of the first object.

### **Transfer Shape Key**

Transfer the active shape key from a different object regardless of its current influence.

Select the object to copy, hold down Shift, then the object to copy into. Use this action and a new shape key will be added to the active object with the active shape of the first object.

### **Delete all Shape Keys**

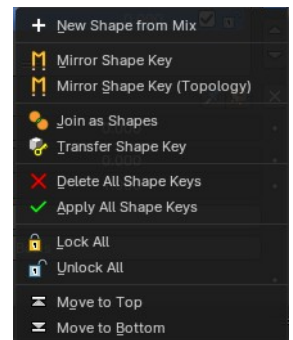

Delete all shape keys at this mesh.

### **Lock All**

Lock all shape keys of the active object. They cannot be editet anymore then.

### **Unlock All**

Unlock all shape keys of the active object.

## Move to Top

Move the shape key to the top of the list. But not above the Basis shape key.

## Move to Bottom

Move the shape key to the bottom of the list.

## Move Shape Key Up / Down

Moves the selected shape key up or down in the list.

Relative Off

## Relative

Set the shape keys to Relative or Absolute.

### Shape Key Lock (pin icon)

Show the active shape in the 3D Viewport without blending. Shape Key Lock gets automatically enabled while the object is in Edit Mode.

### Shape Key Edit Mode (edit mode icon)

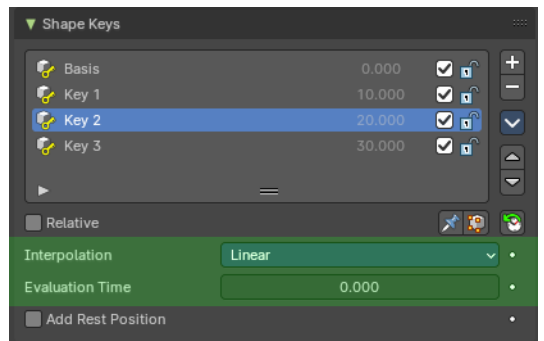

If enabled, when entering Edit Mode the active shape key will not take maximum influence as is default. Instead, the current blend of shape keys will be visible and can be edited from that state.

### Relative unticked

Uses absolute time. The shape changes over time, as defined in its settings.

### Re-Time Shape Keys (clock icon)

Absolute shape keys are timed, by order in the list, at a constant interval. This button resets the timing for the keys. Useful if keys were removed or re-ordered.

## Interpolation

The interpolation method between shape keys.

## Evaluation Time

Evaluate the shape key influence over the defined time. The evaluation starts at influence 0, and reaches 1 at the end of the value of this timer.

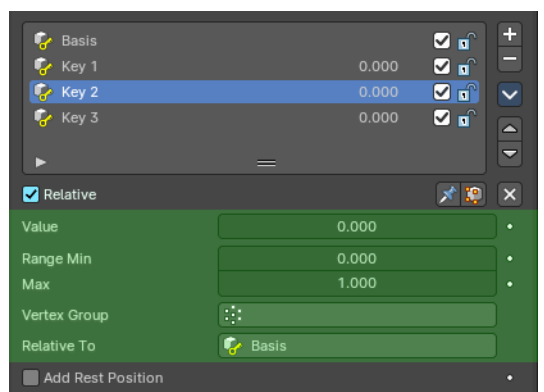

### Relative ticked

The shape is defined relative to the Basis or another specified shape key. And can be adjusted in its settings.

## Value

The weight of the blend between the shape key and its basis key. 0

means no influence, 1 full influence.

## Range

Minimum and maximum range for the influence value of the active shape key.

## Vertex Group

Limit the active shape key deformation to a vertex group.

## Relative To

Select the shape key to deform from. It does not need to be the Basis shape key, but can also be another shape key.

## Add Rest Position

Adds a rest position attribute. It is a copy of the position before shape keys and modifiers are evaluated.

# UV Maps panel

## UV Map

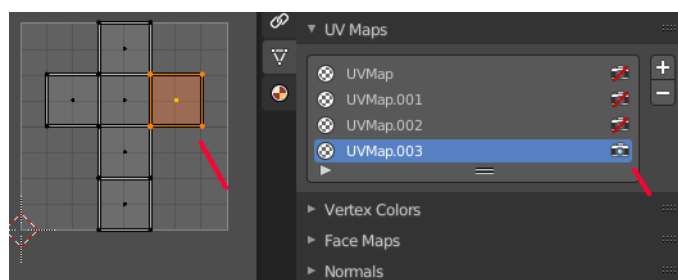

A mesh object can have more than one UV map. Here you can manage the UV maps.

Just one UV map can be active at a time. But you can use secondary UV maps in a material.

## Workflow

A UV map is simply a group of selected UV elements. So select an UV map, set it active by clicking at the Active Render symbol. And select the UV geometry that should be in this UV map.

## Active UV Loop Key Index

A List of the UV maps for this mesh.

It contains two types of shape keys. Basis is the base shape. The other type relies at this shape as the base.

## UV Map name

The name of the shape key. It can be renamed by double clicking at it.

## Active Render

Set this UV map as the one to render. Just one UV map can be active at a time. But you can use secondary UV maps in a material.

## Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## Invert

Exclude the search term instead of searching for it.

## Sort by Name

Sort the List by name.

## Add +

Create a shape key.

## Remove -

Delete the selected shape key.

# Color Attributes panel

In vertex paint mode and sculpt mode you can paint vertices of a mesh with a color. This will create a vertex color index. You can see and manage this vertex color indexes in the Vertex Colors panel.

Vertex colors can for example be used to mix shaders together. Or also directly render them. In the shader editor color attributes can be used by the Attribute node.

A mesh can have more than one vertex color index and type. But just one index can be the active one.

## Active Color Index

A List of the vertex color indexes for this mesh.

## Color index name

The name of the vertex color index. It can be renamed by double clicking at it.

## Active Render

Set this vertex color index as the one to render. Just one vertex color index can be active at a time. But you can use another vertex color index in a material.

## Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## Invert

Exclude the search term instead of searching for it.

## Sort by Name

Sort the List by name.

## Add +

Create a vertex color index.

## Add Color Attribute Specials

### Name

The name of the color attribute index.

### Domain

The domain of the color attribute.

- **Vertex** stores the color attribute data in the vertices of the mesh data
- **Face Corner** stores the color attribute data in the face corners of the mesh data

### Data Type

The the color attribute type.

- **Color** stores RGBA color 32-bit floating point values
- **Byte Color** stores RGBA color 32-bit positive integer values

### Color

The Default fill colour

### Ok

Confirm to apply

### Remove -

Delete the selected vertex color index.

## Specials menu

### Duplicate Color Attribute

Duplicates the selected color attribute

### Convert Color Attribute

Convert a color attribute domain and data type. This tool calls a popup where you can choose what to convert.

## Face Maps panel

Face Maps creates custom gizmos to deform meshes by assigning faces to Face Maps. Face Maps can be used to rig in Object Mode and without making complicated rigging setups.

Face Maps is an experimental implementation. They are currently not fully implemented, and require add-ons to take full advantage of this feature.

### Face Map Index

A List of the face maps for this mesh.

### Face map name

The name of the face maps. It can be renamed by double clicking at it.

### Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

### Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

### *Invert*

Exclude the search term instead of searching for it.

### *Sort by Name*

Sort the List by name.

### Add +

Create a face map.

## Remove -

Delete the selected face map.

## Attributes panel

A list of the attributes at this object. Attributes can be used to identify an object in the shader editor or the geometry nodes editor

## Attributes Index

A List of the attributes for this mesh.

## Attribute name

The name of the attributes. It can be renamed by double clicking at it.

## Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## *Invert*

Exclude the search term instead of searching for it.

## *Sort by Name*

Sort the List by name.

## Add +

Create a new attribute.

## Remove -

Delete the selected attribute.

## Attribute Specials

### Convert Attribute

Change how the selected attribute is stored.

This operator opens a popup menu where you can change the settings of the attribute.

### Mode

What kind of attribute the attribute is.

Just the type generic has further settings.

### Domain

Just generic. What generic mesh element to affect with the attribute.

### Data Type

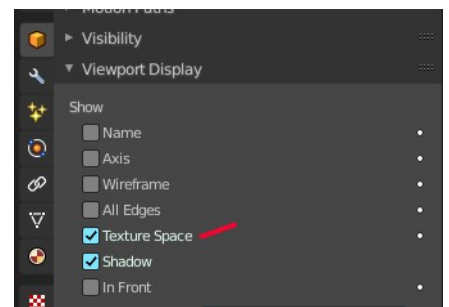

Just Generic. What data type to use for the attribute calculation.

## Texture Space panel

UV mapping can be generated. A procedural brick texture uses generated UV space for example to define the mapping.

In this panel you can adjust settings of the texture space used by generated texture mapping.

The display of the texture space cage can be activated in the Viewport Display in the Object properties.

## Texture Mesh

Use another mesh for texture indices. The vertex of the two objects must be perfectly aligned. Otherwise the UV map will be distorted. Note that, this is only for mesh objects.

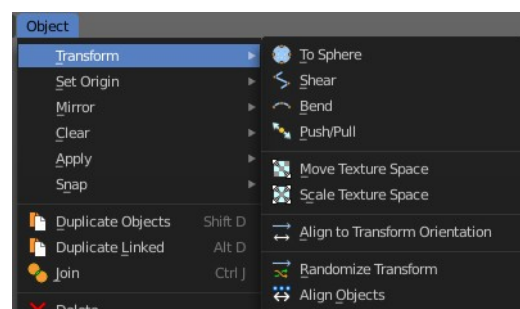

## Auto Texture Space

Adjusts the active object's texture space automatically when transforming the object.

## Location, Size

Adjust the location and size of the texture space manually if Auto Texture Space is off.

The texture space can also be adjusted in the 3D Viewport. See Object Menu / Transform / Move and Scale Texture Space

# Remesh Panel

You may create a sculpt mesh that has ways too many polygons. Or too many polygons at one area, and not enough polygons at another area. Remeshing recreates the mesh geometry, with a more uniform topology.

You need to turn off Dyntopo to activate the feature.

## Mode

Use Voxel or Quad Remesher. The Quad remesher has no settings. The following settings are all for the voxel remesher.

## Voxel Size

Adjust the density of the new created geometry.

## Adaptivity

Reduces the final face count by simplifying geometry where detail is not needed. This method uses tris. A value greater than 0 disables the Fix Poles feature.

## Fix Poles

Produce less poles and a better topology flow.

## Smooth Normals

Smooths the normals of the result.

## Preserve

### Volume

Tries to preserve the volume of the original mesh.

### Attribute

Keep existing paint masks, face sets, vertex color and other generic mesh attributes on the new mesh.

## Voxel Remesh / QuadriFlow Remesh

Starts the remesh in the chosen method.

## Geometry Data panel

Mesh objects can have different types of custom data attached to them. This data is mostly used internally and can be exported by some exporters like Collada or Alembic.

### Clear Sculpt-Mask Data

Removes the sculpting mask data layer. It has no big impact, but this can speed up sculpting if the mask is not longer used.

### Clear Skin Data

Used to manage the skin data layer which is used by the Skin Modifier. This operator can be needed in case a Skin modifier is created but no skin data exist.

### Store Vertex Bevel Weight

Stores the vertex bevel weight so that it is not overwritten by other operations.

## Stores Edge Bevel Weight

Stores the Edge bevel weight so that it is not overwritten by other operations.

## Store Edge Crease

Stores the Edge Crease so that it is not overwritten by other operations.

# Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

## Add

Adds a new property.

## Edit

Opens a panel where you can adjust the settings for the custom property.

## Remove

Removes the property.

## 26.14.2 Editors - Properties Editor - Object Data Properties Tab - Curve Object

## Shape panel

Curve shape related settings.

### Dimensions

By default, new curves are set to be 3D, which means that control points can be placed anywhere in 3D space. Curves can also be set to 2D which constrain the control points to the curve's local XY axis.

### Resolution Preview U / Render U

Defines the number of points between control points. Control points are the points with the handles.

The Preview U setting defines the resolution in the 3D Viewport while the Render U setting defines the render resolution of the curve. If Render U is set to zero (0), then the Preview U setting is used for both the 3D Viewport and render resolution.

### Twist Method

A 3D curve has control points that are not located on the curve's local XY plane. This gives the curve a twist which can affect the curve normals. The three available methods to calculate this twist is Minimum, Tangent and Z-Up.

### Smooth

Interactively removes twists from the curve by smoothing tangents.

### Fill Mode

Fill mode defines the way a curve is displayed when it is beveled.

### Fill Deformed

Fills the curve after applying all modification that might deform the curve. Shape keys and modifiers for example.

### Radius

Causes the deformed object to be scaled by the set curve radius. Utilized when using a curve as a path or when using the Curve Modifier.

### Stretch

The Stretch curve option allows you to let the mesh object stretch, or squeeze, over the entire curve. To get the expected result, use this together with the Bounds Clamp option. Utilized when using the Curve Modifier.

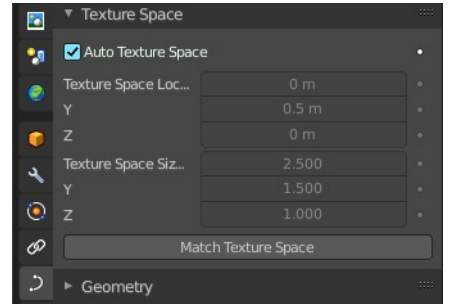

## Bounds Clamp

When this option is enabled, the object and mesh offset along the deformation axis is ignored. This can be useful with the Stretch option or when using a negative axis. Utilized when using the Curve Modifier.

## Texture Space panel

UV mapping can be generated. A procedural brick texture uses generated UV space for example to define the mapping.

In this panel you can adjust settings of the texture space used by generated texture mapping.

The display of the texture space cage can be activated in the Viewport Display in the Object properties.

## Texture Mesh

Use another curve for texture indices. The vertex of the two objects must be perfectly aligned. Otherwise the UV map will be distorted. Note that, this is only for mesh objects.

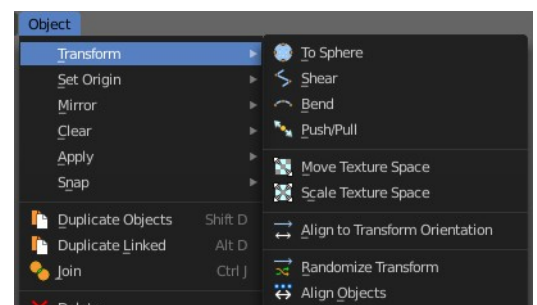

## Auto Texture Space

Adjusts the active object's texture space automatically when transforming the object.

## Location, Size

Adjust the location and size of the texture space manually if Auto Texture Space is off.

The texture space can also be adjusted in the 3D Viewport. See Object Menu / Transform / Move and Scale Texture Space

## Match Texture Space

Match the texture space to the bounding box of the mesh part of the surface object, not the cage.

## Geometry panel

A curve is a spline. And has by default no geometry. But it can have extruded or beveled geometry. This panel allows you to adjust the geometry.

### Offset

Moves the extrusion parallel to the curve normals. Needs extruded geometry first.

### Extrude

Extrude the curve along the positive and negative local Z axes to create a surface. The extrusion direction follows the curve normals.

### Taper Object

Tapers the extruded geometry by using another curve. The taper shape is defined by the Z value of the curve points of the taper object curve. Which you need to manipulate in edit mode.

You might want to rotate the taper object curve by x around 90 degrees to see the shape of the curve in the same view than at the extruded geometry.

The taper object curve:

- Must be an open curve.
- The taper is applied independently to all curves of the extruded object.
- Only the first curve in a Taper Object is evaluated, even if you have several separated segments.
- The scaling starts at the first control point on the left and moves along the curve to the last control point on the right.

- Negative scaling, (e.g. negative local Y on the taper curve) is possible as well. However, rendering artifacts may appear.
- Might need to increase the curve resolution to see more detail of the taper.

With closed curves, the taper curve in Taper Object acts along the whole curve (perimeter of the object), not just the length of the object, and varies the extrusion depth. In these cases, you want the relative height of the Taper Object Taper curve at both ends to be the same, so that the cyclic point (the place where the endpoint of the curve connects to the beginning) is a smooth transition.

## Taper Radius

How the radius of the spline point is computed.

## Map Taper

For curves using a Taper Object and with modifications to the Start/End Bevel Factor. The Map Taper option will then apply the taper to the beveled part of the curve, and not the whole curve.

## Bevel

A curve can not only be extruded, but the extruded geometry can also be beveled to give it a thickness.

There are three bevel methods available. Round adds a rounded bevel. Object adds a bevel in the shape of a chosen object. Profile adds a bevel in the shape of the adjusted curve.

The curve settings becomes active when you have a depth value higher than 0.

## Depth

The size of the bevel.

## Resolution

The subdivision of the bevel.

## Object

Use another curve object to define the shape of the bevel. This curve can be closed, a Bezier circle for example. Or open. Which creates an open bevel shape then.

## Fill Caps

Fills the ends of a beveled curve created by another curve object. And creates a solid object.

## Preset

Type Profile. Curve presets.

## Navigation elements

### Zoom in / out

Zooms in or out in the curve view.

### Tools menu

#### Reset View

Zooms to 100%.

#### Reset Curve

Resets the curve.

### Reverse path

Reverses the path.

### Toggle Profile Clipping

Clamp the values for a curve point between 0 and 1.

## Curve Window

Allows you to modify the curve by dragging the existing curve points and adding new curve points. Adding a curve point can be done by clicking left at the curve. Selected curve points reveals further functionality below the curve window.

### Curve point menu elements

### Handle types

Adjust the handle type of the current active curve point.

### X / Y

The current position of the active curve point.

## Delete points

Delete this curve point.

## Sample straight edges

Sample edges with vector handles.

## Sample even lengths

Sample edges with even lengths.

## Start & End Mapping

### Bevel Start/End

Where to start and to end the bevel relative to the curve. Allows to make a beveled curve which is not fully covered with a bevel.

Increasing the Start Bevel Factor to 0.5 will start beveling the curve 50% of the distance from the start of the curve (in effect shortening the curve). Decreasing the End Bevel Factor by 0.25 will start beveling the curve 25% of the distance from the end of the curve (again, shortening the curve).

### Bevel Mapping Start/End

Allows to control the relation between bevel factors (number between 0 and 1) and the rendered start and end point of a beveled spline. Map the bevel factor to:

### Resolution

To the number of subdivisions of a spline (U resolution).

### Segments

To the length of its segments. Mapping to segments treats the subdivisions in each segment of a curve as if they would have all the same length.

### Spline

The length of a spline.

## Path Animation panel

Move child objects along a path.

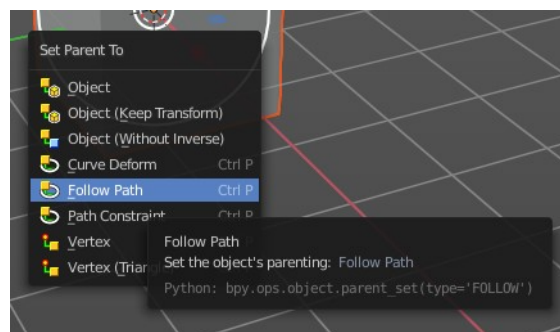

Note! This feature is deprecated, but still available. A more future-proof method is the Follow Path Constraint.

## Workflow

Create a curve. Create an object that you want to move along the path.

Select the object, hold down shift, and parent the object to the curve with the method Follow Path. When you press play then the object will just rotate around itself.

Next select the object, and clear the origin. This will set the object to the start point of the curve. And when you play the animation, then the cube will now move along the curve.

## Frames

The number of frames that are needed to move along the path.

## Evaluation Time

The current frame position. The position is calculated by dividing the frames through the path length.

## Clamp

Clamp the curve path children so that they can't travel past the start and end point of the curve.

## Follow

Make the child object rotate along the curvature of the path.

## Active Spline panel

The Active Spline panel is used in Edit Mode to control properties of the currently selected spline. The tool set for Nurbs curves, Bezier curves and Poly curves differs.

Poly curves can be created by converting mesh geometry to a curve. U stands for the curve direction.

## Bezier curve

### Cyclic U

Closes the active spline.

### Resolution U

Alters the resolution of each segment by changing the number of subdivisions.

### Interpolation Tilt

How the tilt of a segment is calculated.

### Radius

Alters how the radius of a beveled curve is calculated. The effects are easier to see after increasing the radius.

### Smooth

Use Smooth Shading for any 3D geometry.

## Nurbs curve

### Cyclic U

Closes the active spline by connecting the end with the start point.

### Bezier

Make the nurbs curve or surface act like a Bezier spline in the U direction. Order U must be 3 or 4, and Cyclic U must be disabled.

### Endpoint U

Make the end points of the curve meet the end points of the handlers.

### Order U

The area of influence of the control points over the curve. Higher order values means that a single control point has a greater influence over a greater relative proportion of the curve. The valid range of Order values is 2-6, depending on the number of control points present in the curve.

Two, three, four ...

## Resolution U

Alters the resolution of each segment by changing the number of subdivisions.

## Smooth

Use Smooth Shading for any 3D geometry.

## Poly curve

To see this content you need to be in edit mode, and draw a curve with type poly.

## Cyclic U

Closes the active spline.

## Smooth

Use Smooth Shading for any 3D geometry.

# Shape Keys panel

This panel allows you to see and manage shape keys. A shape key is a vertex animation.

Shape keys are for example used for facial animations, when you don't want to use a face rig with bones. The idea is to model a shape key pose for smiling, one for laughing, one for sad, and so on. And then blend the shape key poses together as needed.

Shape keys are also called morph targets or blend shapes.

## Workflow

In Object mode add a shape key. This first shape key is called Basis by default. It is the base for the vertex animation. This basis shape key is the base shape for all further shape keys. It cannot be modified or keyframed.

Now add a second shape key. This second shape key will have more controls so that you can modify it in the needed way.

Enter edit mode with this key 1 selected.

Modify the geometry by moving some vertices around. Shot is from a mesh, but works the same with curves.

Switch back to Object mode.

Have a look at the value slider. This slider defines how the key 1 shape key blends with the Basis shape key.

Move it from value 0 to value 1. You will notice that the vertices that you have modified in Key 1 will now start to move to a new position. Dependent of how strong the value is. With a value of 1 it will be at the position of how you modeled it.

To keyframe this shape click at the Animate property dot behind the slider. The slider will change its color. And the dot will change to a rhombus shape to indicate that there is a keyframe recorded at this frame.

Or you right click at the slider, and choose Insert Keyframe in the menu.

Move to another frame. Change the slider value, and set another keyframe.

Recorded keyframes can be found and further tweaked in the Dope sheet Editor in Shape Key Editor mode. Here you can also record further keyframes under Key / Insert Keyframes. And control the slider values from the channel list.

Add more shape keys and model and animate them as you need them.

## Active Shape Key Index

A List of the shape keys for this mesh.

It contains two types of shape keys. Basis is the base shape. The other type relies at this shape as the base.

## Shape Key name

The name of the shape key. It can be renamed by double clicking at it.

## Slider value

The blend value of this shape key. The Basis shape key does not have such a slider.

## Lock

The lock icon at the end of a group name locks the group from being editable.

## Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## *Invert*

Exclude the search term instead of searching for it.

## *Sort by Name*

Sort the List by name.

## Add +

Create a shape key.

## Remove -

Delete the selected shape key.

## Specials menu

### New Shape From Mix

Add a new shape key with the current deformed shape of the object.

### Mirror Shape Key

Mirror the shape keys on the X axis. This will not work if the mesh vertices is not fully symmetrical.

### Mirror Shape Key (Topology)

Mirror the shape keys on the X axis. But detects the mirrored vertices based on the topology of the mesh. The mesh vertices do not have to be perfectly symmetrical for this action to work.

### Join as Shapes (Transfer Mix)

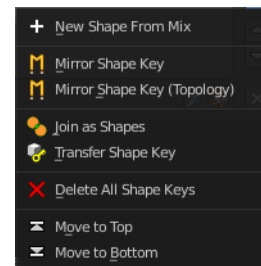

Transfer the current resulting shape from a different object.

Select the object to copy, hold down Shift, then the object to copy into. Use this action and a new shape key will be added to the active object with the current mix of the first object.

### Transfer Shape Key

Transfer the active shape key from a different object regardless of its current influence.

Select the object to copy, hold down Shift, then the object to copy into. Use this action and a new shape key will be added to the active object with the active shape of the first object.

## Delete all Shape Keys

Delete all shape keys at this mesh.

## Move to Top

Move the shape key to the top of the list. But not above the Basis shape key.

## Move to Bottom

Move the shape key to the bottom of the list.

## Move Shape Key Up / Down

Moves the selected shape key up or down in the list.

## Relative

Set the shape keys to Relative or Absolute.

### Relative

The shape is defined relative to the Basis or another specified shape key. And can be adjusted in its settings.

### Shape Key Lock (pin icon)

Show the active shape in the 3D Viewport without blending. Shape Key Lock gets automatically enabled while the object is in Edit Mode.

### Shape Key Edit Mode (edit mode icon)

If enabled, when entering Edit Mode the active shape key will not take maximum influence as is default. Instead, the current blend of shape keys will be visible and can be edited from that state.

### Value

The weight of the blend between the shape key and its basis key. 0 means no influence, 1 full influence.

### Range

Minimum and maximum range for the influence value of the active shape key.

### Vertex Group

Limit the active shape key deformation to a vertex group.

### Relative To

Select the shape key to deform from. It does not need to be the Basis shape key, but can also be another shape key.

## Absolute

The shape changes over time, as defined in its settings.

### Shape Key Lock (pin icon)

Show the active shape in the 3D Viewport without blending. Shape Key Lock gets automatically enabled while the object is in Edit Mode.

### Shape Key Edit Mode (edit mode icon)

If enabled, when entering Edit Mode the active shape key will not take maximum influence as is default. Instead, the current blend of shape keys will be visible and can be edited from that state.

### Re-Time Shape Keys (clock icon)

Absolute shape keys are timed, by order in the list, at a constant interval. This button resets the timing for the keys. Useful if keys were removed or re-ordered.

## Interpolation

The interpolation method between shape keys.

## Evaluation Time

Evaluate the shape key influence over the defined time. The evaluation starts at influence 0, and reaches 1 at the end of the value of this timer.

# Empty Hair object - Attributes Panel

The empty hair object is a special curves object. You control it by geometry nodes.

The Attributes panel allows you to define Attributes for this purpose, which can then be used in the geometry nodes. By default just the position attribute is added.

## List of Attributes

The list of available attributes.

## Add Attributes menu

### radius

Add a radius attribute.

### color

Add a color attribute.

## Custom

Add a custom attribute.

This opens a dialog where you can adjust the parameters of this custom attribute.

## Empty Hair object - Surface Panel

The empty hair object is a special curves object. You control it by geometry nodes.

Define the object that is used as the parent object for the hairs.

## Surface

Which object to use.

## UV Map

Which UV map of the object to use.

## Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

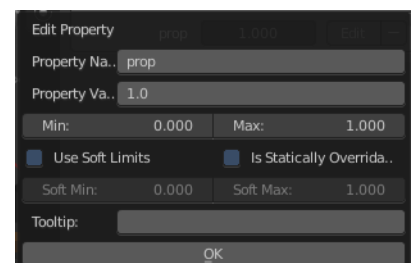

## Add

Adds a new property.

## Edit

Opens a panel where you can adjust the settings for the custom property.

## Remove

Removes the property.

## 26.14.3 Editors - Properties Editor - Object Data Properties Tab - Surface Object

## Shape panel

### Resolution Viewport U / V

The 3D Viewport resolution of the generated mesh. The lower the higher the resolution.

### Render U / V

The rendered resolution of the generated mesh. The lower the higher the resolution.

## Texture Space panel

UV mapping can be generated. A procedural brick texture uses generated UV space for example to define the mapping.

In this panel you can adjust settings of the texture space used by generated texture mapping.

The display of the texture space cage can be activated in the Viewport Display in the Object properties.

## Texture Mesh

Use another curve for texture indices. The vertex of the two objects must be perfectly aligned. Otherwise the UV map will be distorted. Note that, this is only for mesh objects.

## Auto Texture Space

Adjusts the active object's texture space automatically when transforming the object.

## Location and Size X / Y / Z

Adjust the location and size of the texture space manually if Auto Texture Space is off.

The texture space can also be adjusted in the 3D Viewport. See Object Menu / Transform / Move and Scale Texture Space

## Match Texture Space

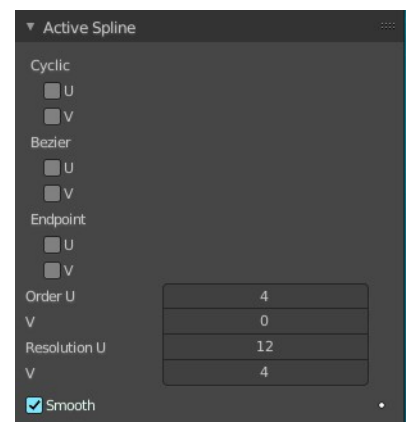

Match the texture space to the bounding box of the mesh part of the surface object, not the cage.

## Active Spline panel

The Active Spline panel is used in Edit Mode to control properties of the currently selected spline.

U and V stands for the surface direction. U goes along the spline. V is the extruding direction.

## Cyclic U / V

Closes the active spline by connecting the end with the start point.

## Bezier U / V

Make the nurbs curve or surface act like a Bezier spline in the U direction. Order U must be 3 or 4, and Cyclic U must be disabled.

## Endpoint U / V

Make the end points of the curve meet the end points of the handlers.

## Order U / V

The area of influence of the control points over the curve. Higher order values means that a single control point has a greater influence over a greater relative proportion of the curve. The valid range of Order values is 2-6, depending on the number of control points present in the curve.

Two, three, four ...

## Resolution U / V

Alters the resolution of each segment by changing the number of subdivisions.

## Smooth

Use Smooth Shading for any 3D geometry.

## Shape Keys panel

This panel allows you to see and manage shape keys. A shape key is a vertex animation.

Shape keys are for example used for facial animations, when you don't want to use a face rig with bones. The idea is to model a shape key pose for smiling, one for laughing, one for sad, and so on. And then blend the shape key poses together as needed.

Shape keys are also called morph targets or blend shapes.

## Workflow

In Object mode add a shape key. This first shape key is called Basis by default. It is the base for the vertex animation. This basis shape key is the base shape for all further shape keys. It cannot be modified or keyframed.

Now add a second shape key. This second shape key will have more controls so that you can modify it in the needed way.

Enter edit mode with this key 1 selected.

Modify the geometry by moving some vertices around. Shot is from a mesh, but works the same with curves.

Switch back to Object mode.

Have a look at the value slider. This slider defines how the key 1 shape key blends with the Basis shape key.

Move it from value 0 to value 1. You will notice that the vertices that you have modified in Key 1 will now start to move to a new position. Dependent of how strong the value is. With a value of 1 it will be at the position of how you modeled it.

To keyframe this shape click at the Animate property dot behind the slider. The slider will change its color. And the dot will change to a rhombus shape to indicate that there is a keyframe recorded at this frame.

Or you right click at the slider, and choose Insert Keyframe in the menu.

Move to another frame. Change the slider value, and set another keyframe.

Recorded keyframes can be found and further tweaked in the Dope sheet Editor in Shape Key Editor mode. Here you can also record further keyframes under Key / Insert Keyframes. And control the slider values from the channel list.

Add more shape keys and model and animate them as you need them.

## Active Shape Key Index

A List of the shape keys for this mesh.

It contains two types of shape keys. Basis is the base shape. The other type relies at this shape as the base.

## Shape Key name

The name of the shape key. It can be renamed by double clicking at it.

## Slider value

The blend value of this shape key. The Basis shape key does not have such a slider.

## Lock

The lock icon at the end of a group name locks the group from being editable.

## Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## *Invert*

Exclude the search term instead of searching for it.

## *Sort by Name*

Sort the List by name.

## **Add +**

Create a shape key.

## **Remove -**

Delete the selected shape key.

## Specials menu

### **New Shape From Mix**

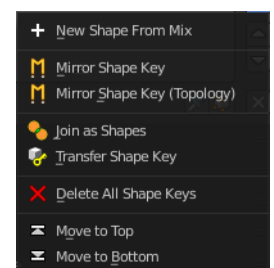

Add a new shape key with the current deformed shape of the object.

### **Mirror Shape Key**

Mirror the shape keys on the X axis. This will not work if the mesh vertices is not fully symmetrical.

### **Mirror Shape Key (Topology)**

Mirror the shape keys on the X axis. But detects the mirrored vertices based on the topology of the mesh. The mesh vertices do not have to be perfectly symmetrical for this action to work.

## Join as Shapes (Transfer Mix)

Transfer the current resulting shape from a different object.

Select the object to copy, hold down Shift, then the object to copy into. Use this action and a new shape key will be added to the active object with the current mix of the first object.

## Transfer Shape Key

Transfer the active shape key from a different object regardless of its current influence.

Select the object to copy, hold down Shift, then the object to copy into. Use this action and a new shape key will be added to the active object with the active shape of the first object.

## Delete all Shape Keys

Delete all shape keys at this mesh.

## Move to Top

Move the shape key to the top of the list. But not above the Basis shape key.

## Move to Bottom

Move the shape key to the bottom of the list.

## Move Shape Key Up / Down

Moves the selected shape key up or down in the list.

## Relative

Set the shape keys to Relative or Absolute.

### Relative

The shape is defined relative to the Basis or another specified shape key. And can be adjusted in its settings.

### Shape Key Lock (pin icon)

Show the active shape in the 3D Viewport without blending. Shape Key Lock gets automatically enabled while the object is in Edit Mode.

### Shape Key Edit Mode (edit mode icon)

If enabled, when entering Edit Mode the active shape key will not take maximum influence as is default. Instead, the current blend of shape keys will be visible and can be edited from that state.

### Value

The weight of the blend between the shape key and its basis key. 0 means no influence, 1 full influence.

## Range

Minimum and maximum range for the influence value of the active shape key.

## Vertex Group

Limit the active shape key deformation to a vertex group.

## Relative To

Select the shape key to deform from. It does not need to be the Basis shape key, but can also be another shape key.

## Absolute

The shape changes over time, as defined in its settings.

## Shape Key Lock (pin icon)

Show the active shape in the 3D Viewport without blending. Shape Key Lock gets automatically enabled while the object is in Edit Mode.

## Shape Key Edit Mode (edit mode icon)

If enabled, when entering Edit Mode the active shape key will not take maximum influence as is default. Instead, the current blend of shape keys will be visible and can be edited from that state.

## Re-Time Shape Keys (clock icon)

Absolute shape keys are timed, by order in the list, at a constant interval. This button resets the timing for the keys. Useful if keys were removed or re-ordered.

## Interpolation

The interpolation method between shape keys.

## Evaluation Time

Evaluate the shape key influence over the defined time. The evaluation starts at influence 0, and reaches 1 at the end of the value of this timer.

# Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

## Add

Adds a new property.

## Edit

Opens a panel where you can adjust the settings for the custom property.

## Remove

Removes the property.

## 26.14.4 Editors - Properties Editor - Object Data Properties Tab - Metaball Object

### Table of content

Metaball panel.....	1

## Metaball panel

### Resolution Viewport

The 3D Viewport resolution of the generated mesh. The lower the higher the resolution.

### Render

The rendered resolution of the generated mesh. The lower the higher the resolution.

### Influence Threshold

How much the surface of a meta object influences the surface of other meta objects. The lower the value the higher the influence, and the bigger the meta element of the meta object.

## Update on Edit

Define how the metas updates on editing.

### Always

Fully display the meta during transformations.

### Half

During transformations, display the meta at half its Wire size resolution.

### Fast

Do not display meta during transformations.

### Never

Never show meta mesh at editing. It is just shown while rendering then.

## Texture Space panel

UV mapping can be generated. A procedural brick texture uses generated UV space for example to define the mapping.

In this panel you can adjust settings of the texture space used by generated texture mapping.

The display of the texture space cage can be activated in the Viewport Display in the Object properties.

## Texture Mesh

Use another curve for texture indices. The vertex of the two objects must be perfectly aligned. Otherwise the

UV map will be distorted. Note that, this is only for mesh objects.

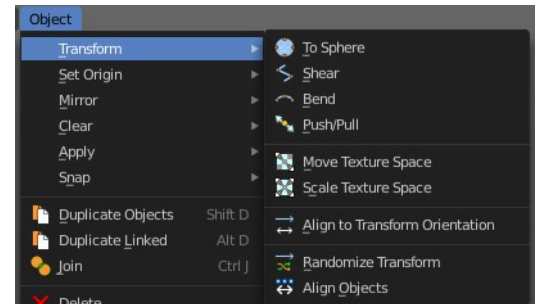

## Auto Texture Space

Adjusts the active object's texture space automatically when transforming the object.

## Location, Size

Adjust the location and size of the texture space manually if Auto Texture Space is off.

The texture space can also be adjusted in the 3D Viewport. See [Object Menu / Transform / Move and Scale Texture Space](#)

## Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

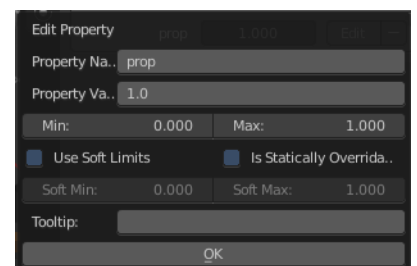

## Add

Adds a new property.

## Edit

Opens a panel where you can adjust the settings for the custom property.

## Remove

Removes the property.

## Shape panel

### Resolution Preview U

The resolution of the text curve geometry in the viewport.

### Render U

The resolution of the text curve geometry when rendering. If Render U is set to zero (0), then the Preview U setting is used for both the 3D Viewport and render resolution.

### Fast Editing

Do not fill the letters in Edit Mode, only show their outline. Object mode display is not affected

### Fill Mode

How to fill the letters. Note that you need to activate Backface culling for back and front in the Viewport Shading to see an effect.

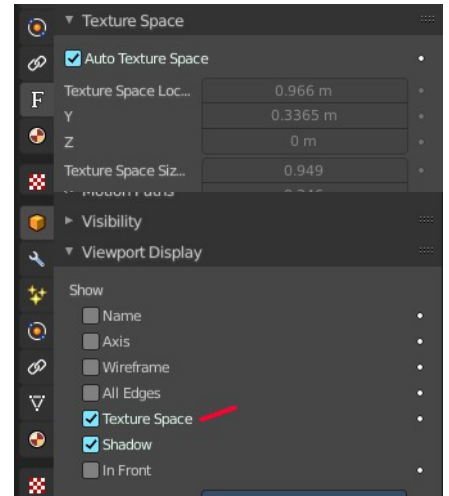

### Fill Deformed

Fill the curve after shape keys and after applying all modifiers.

## Texture Space panel

UV mapping can be generated. A procedural brick texture uses generated UV space for example to define the mapping.

In this panel you can adjust settings of the texture space used by generated texture mapping.

The display of the texture space cage can be activated in the Viewport Display in the Object properties.

## Texture Mesh

Use another curve for texture indices. The vertex of the two objects must be perfectly aligned. Otherwise the UV map will be distorted. Note that, this is only for mesh objects.

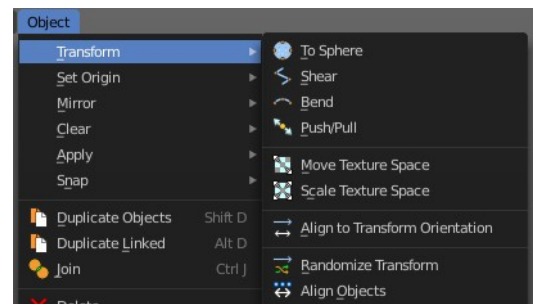

## Auto Texture Space

Adjusts the active object's texture space automatically when transforming the object.

## Location, Size

Adjust the location and size of the texture space manually if Auto Texture Space is off.

The texture space can also be adjusted in the 3D Viewport. See Object Menu / Transform / Move and Scale Texture Space

## Match Texture Space

Match the texture space to the bounding box of the mesh part of the surface object, not the cage.

## Geometry panel

A curve is a spline. And has by default no geometry. The text object differs a bit here since the face is filled. But it has no height. You can have extruded or beveled geometry to add height. This panel allows you to adjust the geometry.

### Offset

Moves the extrusion parallel to the curve normals. Needs extruded geometry first.

### Extrude

Extrude the curve along the positive and negative local Z axes to create a surface. The extrusion direction follows the curve normals.

### Taper Object

Tapers the extruded geometry by using another curve. The taper shape is defined by the Z value of the curve points of the taper object curve. Which you need to manipulate in edit mode.

You might want to rotate the taper object curve by x around 90 degrees to see the shape of the curve in the same view than at the extruded geometry.

The taper object curve:

- Must be an open curve.
- The taper is applied independently to all curves of the extruded object.
- Only the first curve in a Taper Object is evaluated, even if you have several separated segments.
- The scaling starts at the first control point on the left and moves along the curve to the last control point on the right.
- Negative scaling, (e.g. negative local Y on the taper curve) is possible as well. However, rendering artifacts may appear.
- Might need to increase the curve resolution to see more detail of the taper.

With closed curves, the taper curve in Taper Object acts along the whole curve (perimeter of the object), not just the length of the object, and varies the extrusion depth. In these cases, you want the relative height of the Taper Object Taper curve at both ends to be the same, so that the cyclic point (the place where the endpoint of the curve connects to the beginning) is a smooth transition.

## Map Taper

For curves using a Taper Object and with modifications to the Start/End Bevel Factor. The Map Taper option will then apply the taper to the beveled part of the curve, and not the whole curve.

## Bevel

A curve can not only be extruded, but the extruded geometry can also be beveled.

## Depth

The size of the bevel.

## Resolution

The subdivision of the bevel.

## Object

Use another curve object to define the shape of the bevel. This curve can be closed, a Bezier circle for example. Or open. Which creates an open bevel shape then. Be careful with using this at a text object.

## Fill Caps

Fills the ends of a beveled curve created by another curve object. And creates a solid object. Note that this makes for a text object no sense since an n extruded Text object is already a closed object.

## Font panel

Manage the fonts that gets used for the Text object. By default the internal Bfont is used.

You need to load the file for each style separately.

## Regular, Bold, Italic, Bold& Italic

The fonts.

## Data Browser

A list of the available fonts in the scene.

## Name

The name of the active font.

## Number of Users

The number of users for this font.

## Fake User

Keep this font in the scene even if it has no fake user. Note that the builtin Bfont does not require a fake user to stay available.

## Open Font

Load a font.

## Location of Fonts in Windows

C:\Windows\Fonts

## Location of Fonts on Unix

Fonts are typically located under /usr/lib/fonts, or some variant like /usr/lib/X11/fonts, but not always. They may be in other locations as well, such as /usr/share/local or /usr/local/share, and possibly related sub-trees.

## Remove font

Removes the font as the active font. It is still in the list though.

## Style

Edit mode only. Choose what style to use to write the text.

## Transform

### Size

Controls the size of the text.

### Shear

Shears the text.

### Object Font

Allows individual objects to be used to render fonts.

### How to

Create the font characters. Each character can be any object type (mesh, curve, etc.). They must all have a name following the naming schema: “common prefix” followed by the “character name” (“myfont.a”, “myfont.b”,

etc.).

For the text object, enable Instancing Vertices.

In the Font tab, fill the Object Font field with the “common prefix” of your “font” objects. Now, each time a character in your text matches the suffix part of a “font” object’s name, this object is duplicated on this character.

Note! The objects are duplicated so that their center is positioned at the lower right corner of the corresponding characters.

## Text on Curve

Show the text aligned at a curve.

## Underline Position

Shift vertically the position of the underline.

## Underline Thickness

This controls the thickness of the underline.

## Small Caps Scale

The scaling applied to capital letters to turn them into small caps.

# Paragraph panel

## Alignment sub tab

## Horizontal Alignment

How to align the text horizontally.

### Left

Aligns text to the left of the frames when using them, else uses the origin of the text object as the starting point of the text (which grows to the right).

## **Center**

Centers text in the frames when using them, else uses the origin of the text object as the mid-point of the text (which grows equally to the left and right).

## **Right**

Aligns text to the right of the frames when using them, else uses the origin of the text object as the ending point of the text (which grows to the left).

## **Justify**

Only flushes a line when it is terminated by a word-wrap (not by a newline), and uses white-space instead of character spacing (kerning) to fill lines.

## **Flush**

Always flushes the line, even when it is still being typed-in. It uses character spacing (kerning) to fill lines.

Note! Both Justify and Flush only work within frames.

## **Vertical Alignment**

How to align the text vertically.

### **Top Base-Line**

With text boxes, aligns the 'top' base-line of the text to the top of the frames.

With no text box, aligns the actual base-line of the text to the origin of the object, and grows to the bottom.

Note! That difference of reference point in the first line depending on usage of boxes or not is indeed confusing.

### **Top**

With text boxes, aligns the top of the text to the top of the frames.

With no text box, aligns the top of the text to the origin of the object, and grows to the bottom.

### **Center**

With text boxes, centers the text in the frames.

With no text box, centers the text on the origin of the object, and grows in both top and bottom directions equally.

### **Bottom**

With text boxes, align the bottom of the text to the bottom of the frames.

With no text box, align the bottom of the text to the origin of the object, and grows to the top.

### **Bottom Base-Line**

With text boxes, aligns the base-line of the text to the bottom of the frames.

With no text box, aligns the base-line of the text to the origin of the object, and grows to the top.

## Spacing sub tab

### Character Spacing

A factor by which space between each character (kerning) is scaled in width.

In Edit Mode in the 3D View, you can also control individual kerning at text cursor position by pressing Alt-Left / Alt-Right to decrease/increase it.

### Word Spacing

A factor by which white-space between words is scaled in width.

### Line Spacing

A factor by which the vertical space between lines is scaled.

### Offset X/Y

These settings control the X and Y offset of the text position within the object. This applies relatively to the object's origin, either to the whole text or, when using text boxes, to each frame.

## Text Boxes panel

Text boxes (or frames) allow you to distribute the text among rectangular areas within a single text object. You can use more than one box.

The text flows continuously from the lowest-numbered frame to the highest-numbered frame with text inside each frame word-wrapped. It flows between frames when a lower-numbered frame cannot fit any more text.

By increasing size X and Y the text box becomes visible in the viewport by orange lines. A size of 0 means no text box is used.

### Add Text box

Inserts a new frame, just after the current one (in text flow order). The new frame will have the same size and position as the selected one.

### Overflow

How to handle text overflowing available space in the defined boxes.

## Overflow

Just keep text running out of the last box.

## Scale to Fit

Scale text to fit into the available space.

## Truncate

Hide the end of the text that does not fit into the available space.

Note! It will only truncate in Object Mode, in Edit Mode the whole text remains visible (and overflows as needed).

## Text box

### Delete X

Delete the current text box frame.

### Size X/Y

Specifies the width and height of the text box, if set to zero no word-wrap happens (it is ignored, and the whole text box system is disabled if all are set to a null size).

### Offset X/Y

Controls the X and Y offset of the frame, i.e. its position.

## Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

### Add

Adds a new property.

### Edit

Opens a panel where you can adjust the settings for the custom property.

### Remove

Removes the property.

## Grids panel

### List

OpenVDB can contain multiple grids which represent different “layers” of volume. The List Views shows all the grids in the OpenVDB-file along with its name and data type. It is read only.

### Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

### Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

### Invert

Exclude the search term instead of searching for it.

### Sort by Name

Sort the List by name.

## OpenVDB File panel

### File Path

The file path to the vdb file.

### Load File

Load an vdb file.

### Sequence

Load the OpenVDB-file as an animation loading separate files for individual frames. Ticking this checkbox reveals further functionality.

### Frames

Number of frames of the sequence to use.

### Start

Global starting frame of the sequence, assuming the first frame has a 1 in the file name.

### Offset

Offset the number of the frame to use in the animation.

## Sequence Mode

Animation setting of the volume sequence before the start frame and after the end frame.

### **Clip**

Hides frames outside the specified frame range.

### **Extend**

Repeats the start frame before, and the end frame after the frame range.

### **Repeat**

Cycles the frames in the sequence; restarting at frame one.

### **Ping-Pong**

Repeats the frames, reversing the playback direction on every other cycle.

## Viewport Display panel

## Wireframe

Method used to represent volumes in wire frame shading mode. For heavy volume data sets, it can be useful to set the object to always display as wire frame. This way the 3D Viewport remains responsive but the volume still appears in the final render.

## None

The volume is not displayed in wire frame mode.

## Bounds

Displays the volume as bounding box for the entire volume grid.

## Boxes

Displays a bounding boxes for nodes in the volume tree.

## Points

Displays points for nodes in the volume tree.

## Detail

The amount of detail to display for Boxes or Points wire frame mode.

## Course

Display one box or point for each intermediate tree node.

## Fine

Display a box or point for each leaf node containing 8×8 voxels.

## Density

Thickness of the volume in the 3D Viewport. The density of the volume in the render is adjusted via Volume Shading.

## Interpolation

The interpolation method to use for the volumes in solid mode.

## Slice subpanel

Slice the domain object along a single axis.

## Axis

Auto slices the domain object along the view direction. X Y and Z along the world axis.

## Position

The position of the slice.

# Render panel

## Space

Specifies how volume density and step size are computed relative either to the object or world.

## Object

Keeps volume Density and Detail the same regardless of object scale.

## World

Specify Step Size and Density in world space.

## Step Size

Cycles Only.

Distance between volume samples. Lower values render more detail at the cost of performance. If set to zero, the step size is automatically determined based on voxel size.

## Clipping

Cycles Only.

Value under which voxels are considered empty space to optimize rendering.

## Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

## Add

Adds a new property.

## Edit

Opens a panel where you can adjust the settings for the custom property.

## Remove

Removes the property.

## Layers panel

Grease Pencil objects each have a list of 2D layers for grouping and arranging strokes in a List view. Any stroke can only belong to a single 2D layer. There is always only one active layer in the list (the selected one). When you draw, the new strokes are added to the active layer. By default the view order of the layers in the viewport is top to bottom.

Every layer correspond to a channel in the Dope Sheet editor (in Grease Pencil mode). Layers can also be used together with Modifiers to only affects part of your drawing.

### Layer list

#### Layer name

The name of the layer.

#### Mask Layer

Toggle the Masks visibility in the layer.

#### Onion Skinning

Toggle the use the layer for Onion Skinning.

#### Viewport/Render Visibility

Toggle layer visibility in the viewport and in render.

#### Lock

Toggle layer from being editable.

#### Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

#### Add new layer

Adds a new layer.

#### Remove layer

Removes the selected layer.

## Layer Specials

### Duplicate Layer

Makes an exact copy of the selected layer appending a number to differentiate its name.

### Show All

Turns on the visibility of every layer in the list.

### Hide Others

Turns off the visibility of every layer in the list except the active one.

### Lock All

Locks edition of all the layers in the list

### Unlock All

Unlocks edition of all the layers in the list.

### Merge Down

Merge the selected layer with the layer below. The new layer keeps the name of the lower layer.

### Merge All

Merge the selected layer with all layers. The new layer keeps the name of the active layer.

### Copy Layer to Selected

Appends the active layer to the selected object.

### Copy all Layers to Selected

Appends all layers to the selected object.

---

## Move Grease Pencil Layer

Move Grease Pencil Layer up or down.

## Isolate Layer

Hide and lock the layer.

## Isolate Layer

Lock the layer.

## Blend

The layer blending operation to perform. See Color Blend Modes.

## Opacity

Used to set the opacity of the layer.

## Lights

When enabled, the layer is affected by lights.

## Autolock inactive layer

Locks automatically the edition of every layer in the list except the active one. This way you avoid to make unwanted changes in other layers without the need to lock them every time.

## Disallow Locked Materials Editing

Disallow the editing of locked materials.

# Layers panel - Masks subpanel

Use another grease pencil layer as a mask.

## List view

### Name of the grease pencil layer

The name of the layer.

## Invert

Invert the mask.

## Hide

Set mask layer visible or invisible.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## Add

Add a grease pencil layer as a mask layer. The layer must already exist.

## Subtract

Remove the grease pencil layer from the list.

## Move Up / Down

Move the selected grease pencil mask one up or one down.

## Layers panel - Transform subpanel

Allows to transform the current grease pencil layer in the 3d view.

## Layers panel - Adjustment subpanel

### Tint Color

Color that tint any material colors used in the layer.

### Factor

The Factor controls the amount of tint color to apply.

### Stroke Thickness

Thickness value that override the strokes thickness in the layer.

## Layers panel - Relations subpanel

Select a Parent object and Type to manipulate the layer. The layer will inherit the transformations of the parent.

This can be used for rigging for cut-out animation.

## Parent

The Parent object.

## Type

What type of object. When the parent is an armature, then you can choose between object, armature or bone.

## Bone

When the type is a bone, then choose which bone of the armature.

## Pass Index

The layer index number. It can be used with some modifiers to restrict changes to only certain areas.

## View Layer

Defines the View Layer to use for the Grease Pencil layer. If empty, the layer will be included in all View Layers. This is useful to separate drawings parts for compositing.

## Use Masks in Render

Include the mask layer when you render the view layer. You need to have a view layer selected to reveal this option.

# Layers panel - Display subpanel

## Custom Channel Color

Sets the color to use in the channel region of the Dope Sheet.

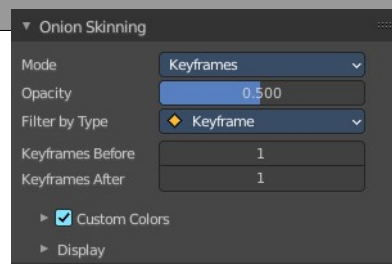

## Show Only On Keyframed

The layer is just visible in the viewport if it has a keyframe in the actual frame.

# Onion Skinning Panel

Onion Skinning show ghosts of the keyframes before and after the current frame. This allows animators to judge and pose in between two frames.

## Mode

### Frames

Shows Frames in the range determined by the Before/After settings.

### Keyframes

Shows Keyframes in the range determined by the Before/After settings.

### Selected

Shows only on the manually selected keyframes in the Dope Sheet.

## Opacity

Control the opacity of the ghost frames.

## Filter By Type

Filters what type of frames to show in the Onion Skinning range.

## Keyframes Before/After

Sets how many frames or keyframes, depending on the Mode, to show before and after the current frame.

## Custom Colors

Before/After

Custom color of the ghost frames before and after the current frame.

## Display

### View in render

Show the onion skinning in final render image e.g. for a motion blur effect.

### Fade

Opacity of the ghosts frames decrease the further away from the current frame.

### Loop

Help working on loop animations showing the first keyframe/frame as ghost when you are on the last frame of your animation.

## Vertex groups panel

A Vertex group is a group of vertices, a selection of the mesh. It is for example used to weight a specific mesh part to a bone. Or to control the growth of hair particles.

This panel allows you to manage and edit vertex groups. Weight painting creates vertex groups automatically.

In Edit mode this panel shows the inactive controls active.

Vertex groups exists for mesh and lattice objects.

## Active Vertex Group list

A List of the vertex groups for this mesh.

### Group name

The name of the group. It can be renamed by double clicking at it.

### Lock

The lock icon at the end of a group name locks the group from being editable.

### Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

### Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

### Invert

Exclude the search term instead of searching for it.

## Sort by Name

Sort the List by name.

## Add +

Create an empty vertex group.

## Remove -

Deletes the active vertex group.

## Move Vertex Group Up

Moves the selected vertex group up in the list.

## Move Vertex Group Down

Moves the selected vertex group down in the list.

## Assign

Assign the selected vertices to the active vertex group.

## Remove

Remove the selected vertices from the active group.

## Select

Select all vertices in the group.

## Deselect

Deselect all vertices in the group.

## Weight

The weight value that gets assigned to the selected vertices.

## Strokes panel

General settings for Grease Pencil strokes.

## Stroke Depth Order

### 2D Layers

The Strokes drawing order respect the order of the 2D layers list (top to bottom) and ignores the real position of the strokes in 3D space. See 2D Layers for more information.

### 3D Location

The strokes drawing order is based on the stroke location in 3D space.

## Stroke Thickness

### World Space

The thickness is relative to world space. Stroke thickness change with the screen zoom factor.

### Screen Space

The thickness is relative to screen space. Stroke thickness remains the same regardless of the screen zoom factor.

### Thickness Scale

Sets a thickness scale factor for all strokes.

### Curve Resolution

The number of segments generated between two control points when editing strokes in curve edit mode.

## Viewport Display panel

Display settings for Edit Lines in Edit Mode and Sculpt Mode.

### Edit Line Color

Sets the color of the Edit Lines.

### Canvas

In 3D space sometimes is difficult to assess on which plane are you drawing. The Canvas is a display overlay helper that shows a grid at the current Drawing Plane. You can enable the Canvas visualization in the Viewport Overlays.

### Color

Color of the Canvas grid lines.

## Scale X/Y

Defines the X and Y scale of the Canvas.

## Offset X/Y

Sets the Canvas position offset from the object's origin.

## Subdivisions

Specifies the number of subdivisions to use for the grid.

# Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

## Add

Adds a new property.

## Edit

Opens a panel where you can adjust the settings for the custom property.

## Remove

Removes the property.

## 26.14.8 Editors - Properties Editor - Object Data Properties Tab - Armature Object

## Pose panel

This panel allows you to turn the display for bone and armature layers on and off.

## Position

Switch between Pose Position and Rest Position.

Pose position shows the armature in the currently posed state.

Rest Position shows the armature in the rest position. In Rest Pose mode there is no posing possible.

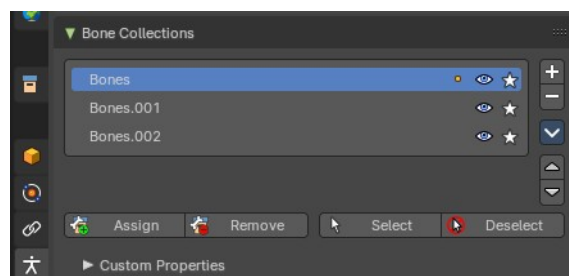

## Bone Collections panel

This panel allows the creation, deletion and editing of Bone Collections.

Bone Collection can be used for bone selections.

Bone Collections is a Pose Mode and Edit Mode feature. The controls will be disabled in Object mode.

**Note:** *Using collection selections, you can then assign a color to the bone group in the Properties Editor > Bone Properties Tab. For example, you can color the left parts of the rig as blue and right parts as red – and you can also assign a color per edit and pose mode.*

## List View

The List view with the bone collections. Double clicking at the name makes it editable.

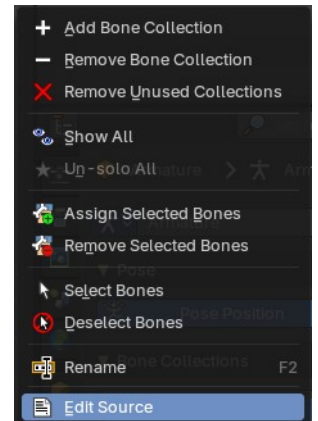

In the list view, you can drag and drop collection order, drag and drop to create child Bone Collections and show/hide collections by using the eye column. You can also Solo a collection by pressing on the star column.

**Note:** *To add a child Bone Collection, which creates a collapsible hierarchy of bone collections, you will need to drag a Bone Collection into a parent Bone Collection. This allows to toggle parent visibility to inherently toggle children visibility.*

## Right click menu at a list item

When you right click at one of the menu items then you will reveal a context menu. All these menu items exists in the regular menu. So we will not explain it here. But explain it in the regular menu entries below.

## Add / Remove

Add or remove a bone collection. To create a child collection, click and drag an existing collection onto a parent collection.

## Bone collection specials

This group of operators show additional options. You can alternatively use the context menu.

## Move Bone Group Up / Down

Move the selected bone group up or down in the list.

## Remove Unused Collections

Removes all empty collections that have no bones assigned to them.

## Show All

Show all collections.

## Un-Solo All

Toggles and clears all Solo stars to show all collections again.

## Rename

Rename the current collection. Note that you can also rename it by simply double clicking at it in the list.

## Assign

Assigns the selected bones to the active bone collection.

**Note:** A bone can belong to multiple collections.

## Remove

Removes the selected bones from the active bone collection.

## Select

Selects the bones in the active bone collection.

## Deselect

Deselects the bones in the active bone collection.

# Motion Paths panel

Motion paths allows you to visualize motion paths of animated bones.

## Workflow

Select the bones that you want to calculate a path for. Note that they should have an animation. No animation, no motion path.

Click at the Calculate button.

When you change the animation then you might need to update the paths.

To remove the paths, click at the X button at the Update paths button.

Note! Remember that only selected bones and their paths are affected by these actions!

The paths are shown in a light shade of gray for unselected points, and a slightly blueish gray for selected ones. Around the current frame a glow indicate the direction of movement: blue towards future frames and green towards the past. Each frame is displayed by a small white dot on the paths.

The paths are automatically updated when you edit your poses/keyframes, and they are also active during animation playback. Playing the animation affects the paths only when the Around Current Frame option is enabled.

## Paths Type

### In Range

Display paths of points within specified range.

## Around Frame

Display paths of points within a fixed number of frames around the current frame. When you enable this button, you get paths for a given number of frames before and after the current one (again, as with ghosts).

## Frame Range Start

The start frame for the paths calculation. (not for Around Current Frame Onion-skinning method).

## End

The end frame for the paths calculation. (not for Around Current Frame Onion-skinning method).

## Step

Display one point for every n frames on the path.

## Bone Cache from

The start frame of the range in which motion paths are shown. You cannot modify this range without deleting the motion path first.

## To

The end frame of the range in which motion paths are shown. You cannot modify this range without deleting the motion path first.

## Calculate ...

Calculate Paths will create a new motion path in cache. It will open a popup where you can adjust the settings.

## Start

The start frame of the path.

## End

The end frame of the path.

## Bake Location

Where to display the path. At the heads of the bones or at the tail of the bones.

## Update Paths

If a path has already been calculated, Update Paths will update the path shape to the current animation. To change the frame range of the calculated path, you need to delete the path and calculate it again.

## Update All Paths

Update all paths will update not just the path for the selected object, but also for all other paths in the object hierarchy.

## Clear Paths

Removes all paths in the hierarchy.

Bone Calculate From and To is internal, and cannot be edited. Just ignore.

## Display subpanel

### Frame Numbers

Show a small number of the corresponding frame next to each frame dot on the path.

### Keyframes

Show the keyframes at the path, with frame number.

### + Non-Grouped Keyframes

For bone motion paths, it searches the whole Action for keyframes instead of in groups with matching name only (this is slower).

### Keyframe Numbers

When enabled, you will see the numbers of the displayed keyframes, so this option is obviously only valid when Show Keys is enabled.

### Lines

Toggles whether the lines between the points are shown.

### Thickness

Customizable thickness for the lines.

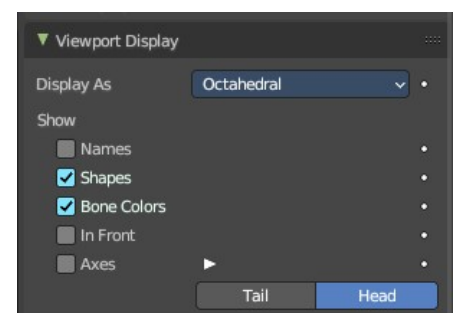

### Custom Color

Custom color for the lines.

## Viewport Display panel

Display options for the armature.

## Display As

How the bones are displayed in the 3D Viewport.

### Octahedral

Bones are displayed as a octahedral. With a thick and a thin end.

### Stick

Bones are displayed as a stick.

### B-Bone

Bones are displayed as a cuboid. This bone display type also allows to display bendy bones subdivisions.

### Envelope

Bones are displayed with its envelopes. The bone deformation influence areas.

### Wire

Bones are displayed as thin wire lines. This bone display type also allows to display bendy bones subdivisions.

### Names

Displays the name of each bone.

## Shapes

When enabled, the default standard bone shape is replaced, in Object Mode and Pose Mode, by the shape of a chosen object (see Shaped Bones for details).

## Bone Colors

Display Bone Collection colors to color the bone, if a color set is assigned in the Bone Tab > Viewport Display panel.

## In Front

Display the armature always in front of mesh objects, even when they are inside.

## Axes

When enabled, the (local) axes of each bone are displayed (only relevant for Edit Mode and Pose Mode).

## Position

You can give the axes widget an offset. Higher values moves the axes more to the tip. Lower values moves the axes more to the root.

## Relations

Display the start point of the relation lines.

## Head

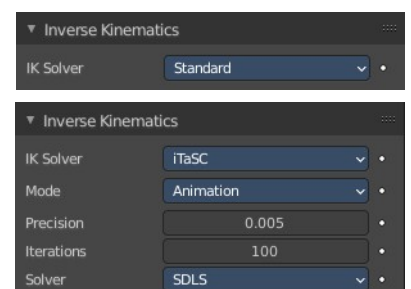

The start position of the relation lines from parent to child bones.

## Tail

The end position of the relation lines from parent to child bones.

## Inverse Kinematics panel

Inverse Kinematics settings.

## IK Solver

The available IK solver solution. Standard and iTaSC.

### Standard

The standard IK solver. It has no further settings.

### iTaSC

iTaSC stands for instantaneous Task Specification using Constraints. It is a generic multi-constraint IK solver. It has more settings and works a bit different than the standard IK solver.

### Mode

The itasc mode. Animation or Simulation.

### Animation

In Animation mode, iTaSC operates like an IK solver: it is stateless and uses the pose from F-curves interpolation as the start pose before the IK convergence. The target velocity is ignored and the solver converges until the given precision is obtained. Still the new solver is usually faster than the old one and provides features that are inherent to iTaSC: multiple targets per bone and multiple types of constraints.

### Precision

The maximum variation of the end effector between two successive iterations at which a pose is obtained that is stable enough and the solver should stop the iterations. Lower values means higher precision on the end effector position.

### Iterations

The upper bound for the number of iterations.

### Solver

Select the inverse Jacobian solver that iTaSC will use.

### SDLS

Computes the damping automatically by estimating the level of ‘cancellation’ in the armature kinematics. This method works well with the Copy Pose constraint but has the drawback of damping more than necessary around the singular pose, which means slower movements. Note that this is only noticeable in Simulation mode.

The SDLS solver does not work together with a Distance constraint. You must use the DLS solver if you are going to have a singular pose in your animation with the Distance constraint.

## DLS

Computes the damping manually. Damping and Epsilon must be tuned for each armature. You should use the smallest values that preserve stability.

### ***Damping Max***

Maximum amount of damping. Smaller values means less damping, hence more velocity and better precision but also more risk of oscillation at singular pose. 0 means no damping at all.

### ***Damping Epsilon***

Range of the damping zone around singular pose. Smaller values means a smaller zone of control and greater risk of passing over the singular pose, which means oscillation.

## Simulation

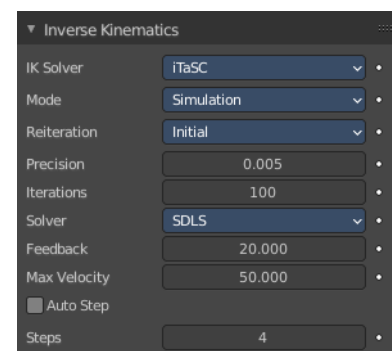

The Simulation mode estimates the target's velocity, operates in a 'true time' context, ignores rotation from keyframes (except via a joint rotation constraint) and builds up a state cache automatically.

### ***Reiteration***

#### **Never**

The solver starts from the rest pose and does not reiterate (converges) even for the first frame. This means that it will take a few frames to get to the target at the start of the animation.

Never will grey out most of the options.

### **Initial**

The solver starts from the rest pose and re-iterates until the given precision is achieved, but only on the first frame (i.e. a frame which doesn't have any previous frame in the cache). This option basically allows you to choose a different start pose than the rest pose and it is the default value. For the subsequent frames, the solver will track the target by integrating the joint velocity computed by the Jacobian solver over the time interval that the frame represents. The precision of the tracking depends on the feedback coefficient, number of substeps and velocity of the target.

### **Always**

The solver re-iterates on each frame until the given precision is achieved. This option omits most of the iTaSC dynamic behavior: the maximum joint velocity and the continuity between frames is not guaranteed anymore in compensation of better precision on the end effector positions. It is an intermediate mode between Animation and real-time Simulation.

## Precision

The maximum variation of the end effector between two successive iterations at which a pose is obtained that is stable enough and the solver should stop the iterations. Lower values means higher precision on the end effector position.

## Iterations

The upper bound for the number of iterations.

## Solver

Select the inverse Jacobian solver that iTaSC will use.

### SDLS

Computes the damping automatically by estimating the level of ‘cancellation’ in the armature kinematics. This method works well with the Copy Pose constraint but has the drawback of damping more than necessary around the singular pose, which means slower movements. Note that this is only noticeable in Simulation mode.

The SDLS solver does not work together with a Distance constraint. You must use the DLS solver if you are going to have a singular pose in your animation with the Distance constraint.

### Feedback

Coefficient on end effector position error to set corrective joint velocity. The time constant of the error correction is the inverse of this value. However, this parameter has little effect on the dynamic of the armature since the algorithm evaluates the target velocity in any case. Setting this parameter to 0 means ‘opening the loop’: the solver tracks the velocity but not the position; the error will accumulate rapidly. Setting this value too high means an excessive amount of correction and risk of instability. The value should be in the range 20-100. Default value is 20, which means that tracking errors are corrected in a typical time of 100-200 ms. The feedback coefficient is the reason why the armature continues to move slightly in Simulation mode even if the target has stopped moving: the residual error is progressively suppressed frame after frame.

### Max Velocity

Indicative maximum joint velocity in radian per second. This parameter has an important effect on the armature dynamic. Smaller value will cause the armature to move slowly and lag behind if the targets are moving rapidly. You can simulate an inertia by setting this parameter to a low value.

### DLS

Computes the damping manually. Damping and Epsilon must be tuned for each armature. You should use the smallest values that preserve stability.

**Feedback**

Coefficient on end effector position error to set corrective joint velocity. The time constant of the error correction is the inverse of this value. However, this parameter has little effect on the dynamic of the armature since the algorithm evaluates the target velocity in any case. Setting this parameter to 0 means ‘opening the loop’: the solver tracks the velocity but not the position; the error will accumulate rapidly. Setting this value too high means an excessive amount of correction and risk of instability. The value should be in the range 20-100. Default value is 20, which means that tracking errors are corrected in a typical time of 100-200 ms. The feedback coefficient is the reason why the armature continues to move slightly in Simulation mode even if the target has stopped moving: the residual error is progressively suppressed frame after frame.

**Max Velocity**

Indicative maximum joint velocity in radian per second. This parameter has an important effect on the armature dynamic. Smaller value will cause the armature to move slowly and lag behind if the targets are moving rapidly. You can simulate an inertia by setting this parameter to a low value.

**Damping Max**

Maximum amount of damping. Smaller values means less damping, hence more velocity and better precision but also more risk of oscillation at singular pose. 0 means no damping at all.

**Damping Epsilon**

Range of the damping zone around singular pose. Smaller values means a smaller zone of control and greater risk of passing over the singular pose, which means oscillation.

**Auto Step**

Let the solver set how many substeps should be executed for each frame.

A sub step is a subdivision on the time between two frames for which the solver evaluates the IK equation and updates the joint position. More substeps means more processing but better precision on tracking the targets. The auto step algorithm estimates the optimal number of steps to get the best trade-off between processing and precision. It works by estimation of the non linearity of the pose and by limiting the amplitude of joint variation during a sub step. It can be configured with the min and max parameters.

**Steps**

Auto Step off. Choose a fixed number of substeps with this parameter. Sub step should not be longer than 10 ms, which means the number of steps is 4 for a 25 fps animation. If the armature seems unstable (vibrates) between frames, you can improve the stability by increasing the number of steps.

**Min**

Auto Step on. Proposed minimum sub step duration (in second). The auto step algorithm may reduce the sub step further based on joint velocity.

## Max

Auto Step on. Maximum sub step duration (in second). The auto step algorithm will not allow sub step longer than this value.

# Selection Sets

This panel allows the creation, deletion and editing of Selection Sets. Bone collections are for edit and pose mode. Selection sets is for pose modes only.

## List View

The List view with the selection sets. Double clicking at the name makes it editable.

In the list view, you can drag and drop collection order, drag and drop to create child Bone Collections and show/hide collections by using the eye column. You can also Solo a collection by pressing on the star column.

**Note:** To add a child Bone Collection, which creates a collapsible hierarchy of bone collections, you will need to drag a Bone Collection into a parent Bone Collection. This allows to toggle parent visibility to inherently toggle children visibility.

## Right click menu at a list item

When you right click at one of the menu items then you will reveal a context menu. The content is the usual entries. So we will not explain it here.

## Add / Remove

Add or remove a selection set.

## Selection Set specials

This group of operators show additional options. You can alternatively use the context menu.

## Delete all Sets

Removes all selection sets.

## Remove selected Bones from all Sets

Remove the selected Bones from all Selection Sets.

## Copy Selection Set(s)

Copies the selected Selection sets.

## Paste Selection Set(s)

Pastes the selected Selection sets.

---

## Move Selection Set Up / Down

Move the selected bone group up or down in the list.

---

## Assign

Assigns the selected bones to the Selection Set.

**Note:** *A bone can belong to multiple collections.*

## Remove

Removes the selected bones from the Selection Set.

## Select

Selects the bones in the Selection Set.

## Deselect

Deselects the selected bones in the Selection Set.

## Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

## Add

Adds a new property.

## Edit

Opens a panel where you can adjust the settings for the custom property.

## Remove

Removes the property.

## Lattice panel

Lattice objects can be used to deform child geometry by the cage of the lattice object.

### Workflow

Create a lattice. Create a mesh object like a sphere.

Parent this sphere at the lattice. With method Lattice deform.

Select the lattice object and enter Edit mode.

Pull the vertices of the lattice cage. And the child geometry will deform.

### Resolution U / V / W

The subdivision resolution of the Lattice object. A resolution of 1 makes the lattice one dimensional.

### Interpolation U / V / W

The interpolation selector for each axis. How the Lattice cage influences the child geometry. Each method gives a slightly different result.

### Outside

Takes only the vertices on the surface of the lattice into account.

### Vertex Group

Apply the influence of the lattice to a vertex group instead of a whole mesh

## Vertex groups panel

A Vertex group is a group of vertices, a selection of the mesh. It is for example used to weight a specific mesh part to a bone. Or to control the growth of hair particles.

This panel allows you to manage and edit vertex groups. Weight painting creates vertex groups automatically.

In Edit mode this panel shows some further controls.

Vertex groups exists for mesh and lattice objects.

### Active Vertex Group list

A List of the vertex groups for this mesh.

#### Group name

The name of the group. It can be renamed by double clicking at it.

#### Lock

The lock icon at the end of a group name locks the group from being editable.

#### Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

#### Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

#### Invert

Exclude the search term instead of searching for it.

#### Sort by Name

Sort the List by name.

#### Add +

Create an empty vertex group.

#### Remove -

Deletes the active vertex group.

## Specials menu

### Sort by Name

Sorts the vertex groups alphabetically by name.

### Sort by Bone Hierarchy

Sorts the vertex groups by the hierarchy of the assigned bones.

### Copy Vertex Group

Add a copy of the active vertex group as a new group. The new group will be named like the original group with “\_copy” appended at the end of its name. And it will contain associations to exactly the same vertices with the exact same weights as in the source vertex group.

### Copy Vertex Groups to Linked

Copy vertex groups of this mesh to all linked objects which use the same mesh data (all users of the data).

### Copy Vertex Group to Selected

Copy all vertex groups to other selected objects provided they have matching indices (typically this is true for copies of the mesh which are only deformed and not otherwise edited).

### Mirror Vertex Group

Mirrors weights and/or flips group names from one side of a symmetrical mesh to the other.

Only mirroring along local X axis is supported. Vertices that have no corresponding vertex on the other side will not be affected. Note, the weights are not transferred to the corresponding opposite bone weight group.

### Mirror Vertex Group (Topology)

Performs the Mirror Vertex Group with the Topology Mirror option enabled.

### Remove from All Groups

Unassigns the selected vertices from all groups. Even locked.

### Clear Active Group

Remove all assigned vertices from the active group. The group is made empty. Note that the vertices may still be assigned to other vertex groups of the object. This feature does not affect locked groups.

### Delete All Unlocked Groups

Remove all vertex groups from the object that are not locked.

## Delete All Groups

Remove all vertex groups from the object.

## Lock All

Lock all groups.

## Unlock All

Unlock all groups.

## Lock Invert All

Invert group locks.

## Move Vertex Group Up / Down

Moves the selected vertex group up or down in the list.

## Assign

Assign the selected vertices to the active vertex group.

## Remove

Remove the selected vertices from the active group.

## Select

Select all vertices in the group.

## Deselect

Deselect all vertices in the group.

## Weight

The weight value that gets assigned to the selected vertices.

## Set Active Group

Lets you select the group that will become the active one (menu only).

## Shape Keys panel

This panel allows you to see and manage shape keys. A shape key is a vertex animation.

Shape keys are for example used for facial animations, when you don't want to use a face rig with bones. The idea is to model a shape key pose for smiling, one for laughing, one for sad, and so on. And then blend the shape key poses together as needed.

Shape keys are also called morph targets or blend shapes.

## Workflow

In Object mode add a shape key. This first shape key is called Basis by default. It is the base for the vertex animation. This basis shape key is the base shape for all further shape keys. It cannot be modified or keyframed.

Now add a second shape key. This second shape key will have more controls so that you can modify it in the needed way.

Enter edit mode with this key 1 selected.

Modify the geometry by moving some vertices around.

Switch back to Object mode.

Have a look at the value slider. This slider defines how the key 1 shape key blends with the Basis shape key.

Move it from value 0 to value 1. You will notice that the vertices that you have modified in Key 1 will now start to move to a new position. Dependent of how strong the value is. With a value of 1 it will be at the position of how you modeled it.

To keyframe this shape click at the Animate property dot behind the slider. The slider will change its color. And the dot will change to a rhombus shape to indicate that there is a keyframe recorded at this frame.

Or you right click at the slider, and choose Insert Keyframe in the menu.

Move to another frame. Change the slider value, and set another keyframe.

Recorded keyframes can be found and further tweaked in the Dope sheet Editor in Shape Key Editor mode. Here you can also record further keyframes under Key / Insert Keyframes. And control the slider values from the channel list.

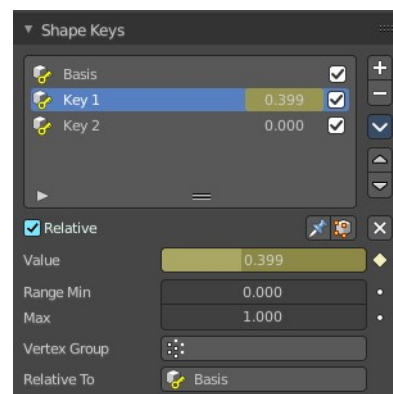

Add more shape keys and model and animate them as you need them.

## Active Shape Key Index

A List of the shape keys for this mesh.

It contains two types of shape keys. Basis is the base shape. The other type relies at this shape as the base.

## Shape Key name

The name of the shape key. It can be renamed by double clicking at it.

## Slider value

The blend value of this shape key. The Basis shape key does not have such a slider.

## Lock

The lock icon at the end of a group name locks the group from being editable.

## Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## Invert

Exclude the search term instead of searching for it.

## Sort by Name

Sort the List by name.

## Add +

Create a shape key.

## Remove -

Delete the selected shape key.

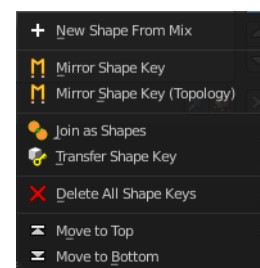

## Specials menu

### New Shape From Mix

Add a new shape key with the current deformed shape of the object.

### Mirror Shape Key

Mirror the shape keys on the X axis. This will not work if the mesh vertices is not fully symmetrical.

## Mirror Shape Key (Topology)

Mirror the shape keys on the X axis. But detects the mirrored vertices based on the topology of the mesh. The mesh vertices do not have to be perfectly symmetrical for this action to work.

## Join as Shapes (Transfer Mix)

Transfer the current resulting shape from a different object.

Select the object to copy, hold down Shift, then the object to copy into. Use this action and a new shape key will be added to the active object with the current mix of the first object.

## Transfer Shape Key

Transfer the active shape key from a different object regardless of its current influence.

Select the object to copy, hold down Shift, then the object to copy into. Use this action and a new shape key will be added to the active object with the active shape of the first object.

## Delete all Shape Keys

Delete all shape keys at this mesh.

## Move to Top

Move the shape key to the top of the list. But not above the Basis shape key.

## Move to Bottom

Move the shape key to the bottom of the list.

## Move Shape Key Up / Down

Moves the selected shape key up or down in the list.

## Relative

Set the shape keys to Relative or Absolute.

### Relative

The shape is defined relative to the Basis or another specified shape key. And can be adjusted in its settings.

### Shape Key Lock (pin icon)

Show the active shape in the 3D Viewport without blending. Shape Key Lock gets automatically enabled while the object is in Edit Mode.

### Shape Key Edit Mode (edit mode icon)

If enabled, when entering Edit Mode the active shape key will not take maximum influence as is default. Instead, the current blend of shape keys will be visible and can be edited from that state.

## Value

The weight of the blend between the shape key and its basis key. 0 means no influence, 1 full influence.

## Range

Minimum and maximum range for the influence value of the active shape key.

## Vertex Group

Limit the active shape key deformation to a vertex group.

## Relative To

Select the shape key to deform from. It does not need to be the Basis shape key, but can also be another shape key.

## Absolute

The shape changes over time, as defined in its settings.

## Shape Key Lock (pin icon)

Show the active shape in the 3D Viewport without blending. Shape Key Lock gets automatically enabled while the object is in Edit Mode.

## Shape Key Edit Mode (edit mode icon)

If enabled, when entering Edit Mode the active shape key will not take maximum influence as is default. Instead, the current blend of shape keys will be visible and can be edited from that state.

## Re-Time Shape Keys (clock icon)

Absolute shape keys are timed, by order in the list, at a constant interval. This button resets the timing for the keys. Useful if keys were removed or re-ordered.

## Interpolation

The interpolation method between shape keys.

## Evaluation Time

Evaluate the shape key influence over the defined time. The evaluation starts at influence 0, and reaches 1 at the end of the value of this timer.

# Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

## Add

Adds a new property.

## Edit

Opens a panel where you can adjust the settings for the custom property.

## Remove

Removes the property.

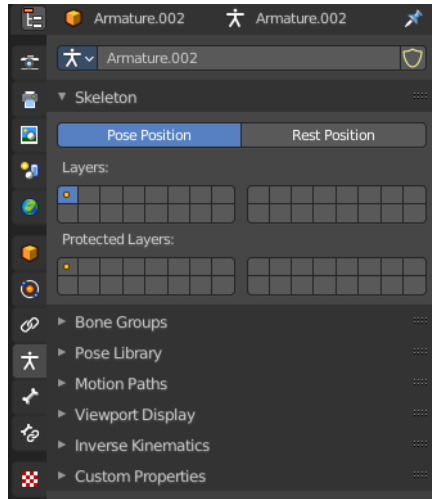

## 26.14 Editors - Properties Editor - Object Data Properties Tab

### Table of content

Properties Editor - Object Data Tab.....	1

## Properties Editor - Object Data Tab

In the object data tab you will find all the object specific data settings. For a mesh object vertex groups and shape keys for example. An armature object will show armature related settings.

The icon can differ. For a mesh object you will have a vertice icon. For an armature object you will have a armature icon.

And the content of the panels can differ, dependent of the mode you are in. Some tools just shows in edit mode. Assign / Remove tools for vertex groups for example.

### Data Browser

Lists the available mesh data of objects of same type. And allows to choose another mesh data of the same type.

## Name

The name of the **Mesh data** of the currently active object. You can also use the mesh data from other objects of the same type.

By default the name of the mesh data is the same than the object name. But it can be renamed.

## Fake User

Add a fake user to this object so that it is not deleted when it has no user in the scene.

# Custom Properties panel

This panel exists for all object types in the Object Data Properties. Allows you to add custom properties that can be used in various ways then. For scripting, or to drive animation etc.

In this panel you might also find custom properties from addons or scripts.

## Add

Adds a new property.

## Property Value

The value of the property.

## Edit

Opens a panel where you can adjust the settings for the custom property. The settings should be self explaining.

## Remove

Removes the property.

## Preface

Materials controls the appearance of meshes, curves, volumes and other objects.

A material is the container that contains all the necessary data to define the look of an object. It is made of a code part, the shaders. They control how the surface reacts. And color data like textures. A black and white texture can also control what areas of a shader reacts in what way. Like a gloss map.

Materials can be created in either the Material properties, or in the Shader Editor. The content that is displayed is the same. But the way how it is represented is different.

Materials can be assigned to one or more objects, and different materials can be assigned to different parts of meshes.

The material system is built with physically-based rendering in mind. But can also be used to create toon style materials.

## Affected Renderer

The material system is for Eevee and Cycles. Workbench renderer is meant for fast preview display. It does not use materials like Eevee or Cycles. All you can choose is a color.

Eevee and Cycles have nearly the same nodes available. But some nodes differ. Eevee is a realtime renderer. Cycles is a physically based render. That's two different approaches. So you should take that into account when creating the materials.

## Material header

The header area contains the list of materials and the functionality to create new materials and to remove them.

Note that a material for a grease pencil object differs from the rest. It is basically the same. But grease pencil objects have other icons in the material browser.

## Material List

The list of assigned materials to this object. The list shows the material slots. A material slot that has the red material icon assigned has no material content yet. It is just an empty slot. You have to create it first by clicking at the New button below, in the material property.

Clicking at the name allows renaming of the material.

Grease pencil materials have additional functionality in the list.

## Show in ghosts

Turn on onion skinning for this material. Onion skinning displays strokes before and after the current frame.

## Hide

Show or hide the material.

## Locked

Protect color from further editing.

## Drag Handler

The two vertical lines at the end is a handler with which you can expand the list.

## Search Field

You can expand a search field at the bottom of the list. Type in your term and hit enter to filter for your term.

## Sort by Name

Sort the List by name.

## Reverse

Exclude the search term instead of searching for it.

## Add Material Slot

Add a new material slot

## Remove Material Slot

Remove the selected material slot.

## Materials Specials menu

### With a mesh or curve or other object type

#### ***Copy Material***

Copy the material settings and nodes.

#### ***Copy Material to selected***

Copy material to selected objects. First select the object without material. Hold down shift and select the object with material. Perform Copy material to selected.

#### ***Paste Material***

Pastes a copied material.

#### ***Remove Unused Slots***

Remove material slots that does not contain a material.

### With a grease pencil stroke object

#### ***Show All***

Show all materials.

#### ***Hide Others***

Hide unselected materials.

#### ***Lock All***

Lock all materials from editing.

#### ***Unlock All***

Unlock all materials.

#### ***Lock Unused***

Lock unused materials from editing.

#### ***Remove Unused Slots***

Remove material slots that does not contain a material.

#### ***Merge Similar***

Merge similar materials in stroke.

#### ***Convert Materials to Vertex Colors***

Grease pencil strokes can have either vertex colors or material colors. This feature converts the selected materials to a vertex color palette.

## ***Extract Palette from Vertex Color***

Grease pencil strokes can have either vertex colors or material colors. This feature converts a vertex color palette to materials.

## **Append Active Layer to Object**

Appends the active layer to an object.

## **Append all Layers to Object**

Appends all layer to an object.

---

## **Material data property**

## **Material Browser**

A list of the available materials in the scene where you can choose a material from.

## **New**

When the object has no material yet. Creates a new default material and adds a first material slot to the list.

## **Name**

The name of the active material. Double clicking allows to rename it.

## **Fake User**

Keep this data even when it has no user in the scene.

## **New**

Creates a new default material, and assigns it to the active material slot.

## **Remove**

## **Link**

Specifies whether the material is to be linked to the Object or to the Object Data.

Different objects may share the same mesh data. And if the material is linked to the mesh, every object will share it. If the material is linked directly to the object data, the objects can have different materials and still share the same mesh. Default is Data.

## **Right Click menus**

When you right click at the material property then you will reveal context menus with different content, dependant of where you click. Most of the content is explained in chapter 6, the general right click menu functionality. The rest should be self explaining.

## Edit Mode

In Edit mode you can assign different materials at different mesh or curve parts.

## Workflow

Enter Edit Mode. Select the material that you want to assign. Select the mesh or curve part. Click at the assign button.

## Assign

Assign active material slot and material to the selected faces in the mesh, strokes in a Grease Pencil, and similar for other object types.

## Select

Select faces assigned to the active material slot.

## Deselect

Deselect faces assigned to the active material slot.

# Preview Panel

A preview window to judge the material.

## Flat, Sphere, Cube, etc.

Different shaped preview objects.

## Preview World

Include the world settings into the preview rendering.

# Surface Panel

This panel displays the Surface part of the material as a list. And allows you to edit its values.

## Use Nodes

Choose if you want to use nodes or not. Unticked it will use a default material with just basic values. Ticked it will use the material as defined in the shader editor in the Shading workspace. And display its values.

The values with unticked Use Nodes will not appear in the material node editor.

## Use Nodes unticked with Eevee

Gives you the values for a very basic PBR realtime shader.

## Use Nodes unticked with Cycles

Gives you a base color.

## Use Nodes ticked

Displays the content of the material in the shader editor as a list.

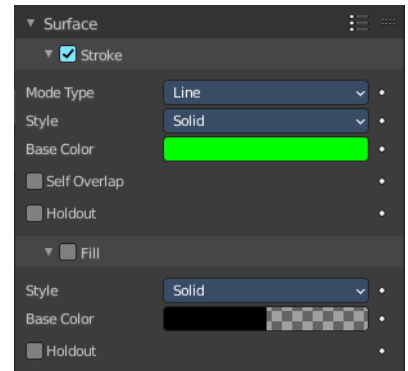

Triangle buttons indicates that there is a node connected to this input. You can expand this triangle to access the values of the connected node.

For the nodes and the values please have a look in the shader editor.

# Surface Panel - Grease Pencil Object

The content of the surface panel with a grease pencil object is a bit different from other object types since Grease pencil objects uses materials for the drawing color.

## Presets

The presets in the header allows you to use and store presets.

## Stroke Subpanel

Stroke related settings.

### Mode Type

The draw mode for the stroke. The modes should be self explaining. Most settings are the same in all modes.

### Mode Type Line

### Style

The draw style.

### Solid

#### Base Color

The color of the stroke.

### Texture

#### Base Color

The base color of the stroke. You can blend the texture with this color.

### Image Prop

This property contains the list of loaded images. When no image is loaded then it displays the Open Buttons. When an image exists then it displays the name of the currently selected image.

From left to right ...

### **Image browser**

This is a list of the images in the scene. This list allows you to switch to other images.

### **Search form**

Search for specific images.

### **Image Edit Box**

Read the name of the currently selected image. And you can rename the image here too.

### **Number of Fake Users**

In case this file has a fake user assigned, then this number displays the number of fake users.

### **Fake User**

With this button you assign a fake user to this selected image.

Data, like images, that is not longer linked to anything else gets removed when you save and reload a scene. Bforartists has the concept of fake users to go around this behavior. An image with a fake user is in fact linked to something. And so it is not lost when you save and reload the scene.

### **Open**

Open a new image.

### **Remove**

Removes the image.

### **Self Overlap**

Disable stencil and allow self intersections with alpha materials.

### **Holdout**

Remove the color from underneath this stroke by using the stroke as a mask.

## **Mode Type Dots + Squares**

### **Style**

The draw style.

### **Solid**

#### **Base Color**

The color of the stroke.

## **Texture**

### **Base Color**

The base color of the stroke. You can blend the texture with this color.

### **Image Prop**

This property contains the list of loaded images. When no image is loaded then it displays the Open Buttons. When an image exists then it displays the name of the currently selected image.

From left to right ...

### **Image browser**

This is a list of the images in the scene. This list allows you to switch to other images.

### **Search form**

Search for specific images.

### **Image Edit Box**

Read the name of the currently selected image. And you can rename the image here too.

### **Number of Fake Users**

In case this file has a fake user assigned, then this number displays the number of fake users.

### **Fake User**

With this button you assign a fake user to this selected image.

Data, like images, that is not longer linked to anything else gets removed when you save and reload a scene. Bforartists has the concept of fake users to go around this behavior. An image with a fake user is in fact linked to something. And so it is not lost when you save and reload the scene.

### **Open**

Open a new image.

### **Remove**

Removes the image.

### **Alignment**

Dots and Squares mode.

### **Path**

Alignment follows stroke drawing path and object rotation.

### **Object**

Alignment follows object rotation only.

### **Fixed**

Keeps aligned with viewport.

## Self Overlap

Disable stencil and allow self intersections with alpha materials.

## Rotation

Additional rotation applied to dot and square strokes.

## Holdout

Remove the color from underneath this stroke by using the stroke as a mask.

---

## Fill Subpanel

Fill color related settings.

## Style

### *Solid*

### Base Color

The color of the stroke.

### Holdout

Remove the color from underneath this stroke by using the stroke as a mask.

---

## Gradient

### Gradient Type

Draw a linear or a radial gradient.

### Base Color

The first color of the gradient.

### Secondary Color

The second color of the gradient.

### Blend

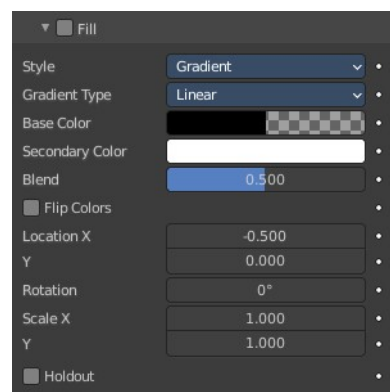

The mix factor between the first and second gradient color.

### Flip Colors

Flip the filling colors.

### Location X / Y

The location of the gradient.

## Rotation

The rotation of the gradient.

## Scale X / Y

The scale of the gradient.

## Holdout

Remove the color from underneath this stroke by using the stroke as a mask.

---

## Texture

### **Base Color**

The base color of the stroke. You can blend the texture with this color.

### **Image Prop**

This property contains the list of loaded images. When no image is loaded then it displays the Open Buttons. When an image exists then it displays the name of the currently selected image.

From left to right ...

### **Image browser**

This is a list of the images in the scene. This list allows you to switch to other images.

### **Search form**

Search for specific images.

### **Image Edit Box**

Read the name of the currently selected image. And you can rename the image here too.

### **Number of Fake Users**

In case this file has a fake user assigned, then this number displays the number of fake users.

### **Fake User**

With this button you assign a fake user to this selected image.

Data, like images, that is not longer linked to anything else gets removed when you save and reload a scene. Bforartists has the concept of fake users to go around this behavior. An image with a fake user is in fact linked to something. And so it is not lost when you save and reload the scene.

## Open

Open a new image.

## Remove

Removes the image.

## Location X / Y

The location of the image.

## Rotation

The rotation of the image.

## Scale X / Y

The scale of the image.

## Clip Image

Do not repeat the image, but clamp it to one instance.

## Holdout

Remove the color from underneath this stroke by using the stroke as a mask.

# Volume Panel

This panel displays the Volume part of the material as a list. And allows you to edit its values.

## Use Nodes

Choose if you want to use a volume node or not.

Removing the volume node in the shader editor will clear the volume panel.

# Displacement Panel

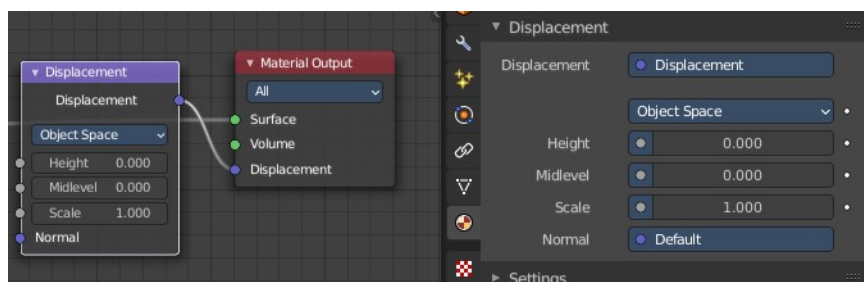

This panel displays the Displacement part of the material as a list. And allows you to edit its values.

## Use Nodes

Choose if you want to use a displacement node or not.

Removing the displacement node in the shader editor will clear the panel.

## Settings Panel - Eevee (Legacy) renderer

### Backface Culling

Use back face culling to hide the back side of faces.

### Blend Mode

The blend mode for transparent faces.

### Opaque

Render surface without transparency.

### Alpha Clip

Use the alpha threshold to clip the visibility. On or off.

### Clip threshold

A pixel is just rendered if the value is higher than this clip threshold. This threshold is the same for blend mode and shadow mode.

### Alpha Hashed

Use Noise to dither the binary visibility. Works best with multi samples.

### Alpha Blend

Render polygons transparent, dependent of the alpha channel of the texture.

### Shadow Mode

### None

Material will cast no shadow.

## Opaque

Material will cast shadow without transparency.

## Alpha Clip

Use the alpha threshold to clip the visibility. On or off.

## Clip threshold

A pixel is just rendered if the value is higher than this clip threshold. This threshold is the same for blend mode and shadow mode.

## Alpha Hashed

Use Noise to dither the binary visibility.

## Show Backface

With Blend Mode Alpha Blend. Limit the transparency to a single layer to avoid transparency layer sort problems.

## Screen Space Refraction

Use ray traced screen space refraction.

## Refraction depth

The thickness of the object to compute two refraction event. 0 means disabled.

## Subsurface Translucency

Add translucency effect to subsurface.

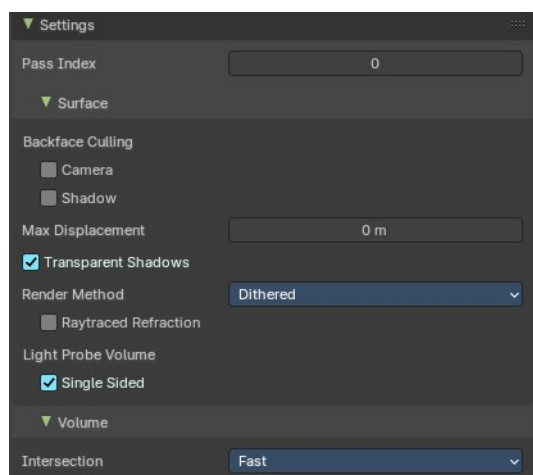

## Pass Index

Index number for the material index render pass.

# Settings Panel - Eevee renderer

## Pass Index

Index number for the material index pass.

## Surface subpanel

### Backface Culling

#### **Camera**

Use back face culling to hide the back side of faces.

#### **Shadow**

Use back face culling when casting shadows.

### Max displacement

The maximum distance that a vertex can be displaced. Displacement over this threshold may cause visibility issues.

### Transparent Shadows

Use transparent shadows for this material.

### Render method

#### **Dithered**

Allows for grayscale hashed transparency, and is compatible with render passes and raytracing. This is also known als deferred rendering.

#### **Raytraced refraction**

Use raytracing to determine refracted color instead of using only light probes. This prevents the surface from contributing to the lighting of surfaces not using this setting.

#### **Blended**

Allows for colored transparency, but is incompatible with render passes and raytracing. This is also known als forward rendering.

### Transparency Overlap

Render multiple transparent layers. Note that this may introduce transparency sorting problems.

### Light Probe Volume

#### **Single Sided**

Consider materials single sided for light probe volume capture.

## Volume subpanel

### Intersection

#### **Fast**

Each face is considered as a medium interface. It gives correct results for manifold geometry that contains no inner parts.

#### **Accurate**

Faces are considered as a medium interface only when they have different consecutive facing. It gives correct results as long as the max ray depth is not exceeded. This method also has a significant higher memory requirement.

## Settings Panel - Cycles renderer

Material settings.

### Pass Index

The index number of this material. This material index can be used for masking in post processing for example.

### Surface

Surface related settings.

#### Multiple Importance

By default lights use only direct light sampling. Which can be noisy with sharp glossy reflections. Multiple Importance activates Indirect light sampling to reduce noise.

#### Transparent Shadows

Use transparent shadows if the material contains a transparent bsdf node.

#### Displacement

What method to use for displacement.

### Volume

#### Sampling

What sampling method to use for volume rendering.

## Interpolation

What interpolation method to use for volume rendering.

## Homogeneous

Assume to have a homogeneous volume to speed up rendering.

## Step rate

Scale the distance between volume shader samples when rendering the volume. Lower values increases accuracy and render time.

Step rate becomes dysfunctional when Homogeneous is activated.

# Line Art

## Material Mask

Use material masks to filter out occluded strokes. You can filter out up to eight mask bits. The index starts with 0.

## Levels

Faces with this material will behave as if it has set numbers of layers in occlusion.

## Intersection Priority

Overwrite object and collection priority value.

## Intersection Priority Value

The intersection line will be included into the object with the higher intersection priority value.

# Viewport Display

Display settings for viewport display mode Solid. The items should be self explaining.

## Settings

Cycles only. And with Cycles these settings are just relevant for the viewport rendering in Material Preview mode. That's why they are in the viewport display panel.

## Backface Culling

Use back face culling to hide the back side of faces.

## Blend Mode

The blend mode for transparent faces.

### Opaque

Render surface without transparency.

### Alpha Clip

Use the alpha threshold to clip the visibility. On or off.

### *Clip threshold*

A pixel is just rendered if the value is higher than this clip threshold. This threshold is the same for blend mode and shadow mode.

### Alpha Hashed

Use Noise to dither the binary visibility. Works best with multi samples.

### Alpha Blend

Render polygons transparent, dependent of the alpha channel of the texture.

## Shadow Mode

### None

Material will cast no shadow.

### Opaque

Material will cast shadow without transparency.

### Alpha Clip

Use the alpha threshold to clip the visibility. On or off.

### *Clip threshold*

A pixel is just rendered if the value is higher than this clip threshold. This threshold is the same for blend mode

and shadow mode.

## Alpha Hashed

Use Noise to dither the binary visibility.

## Show Backface

With Blend Mode Alpha Blend. Limit the transparency to a single layer to avoid transparency layer sort problems.

## Screen Space Refraction

Use ray traced screen space refraction.

## Refraction depth

The thickness of the object to compute two refraction event. 0 means disabled.

## Subsurface Translucency

Add translucency effect to subsurface.

## Pass Index

Index number for the material index render pass.

# Custom Properties panel

This panel exists for all object types in the Object Data Properties. Allows you to add custom properties that can be used in various ways then. For scripting, or to drive animation etc.

In this panel you might also find custom properties from addons or scripts.

## Add

Adds a new property.

## Property Value

The value of the property.

## Edit

Opens a panel where you can adjust the settings for the custom property. The settings should be self explaining.

## Remove

Removes the property.

## Properties Editor - Texture Tab

In this panel you can create or load textures for the brushes in the image painting modes. Note that with the Workbench renderer you have less options.

### Brush drop down box

What kind of brush texture you want to create. A brush texture, or a brush mask texture. Brush textures appears in the texture panel of the brush settings. Brush mask textures appears in the texture mask panel of the brush settings.

### Texture property

#### Texture browser

A texture browser with the available textures.

#### Edit Box

The name of the currently active palette. You can also rename the palette here. A click into the edit box makes the name editable.

#### Number of users

See how many users the palette currently has.

#### Fake User

Fake User sets the element to have a fake user. Data without a user is normally not saved. But sometimes you want to force the data to be kept even when the data block has no user.

## New Texture

Add a new texture

## Remove Texture

Removes the texture as the active texture. Note that the texture is still in the list.

## Type

The image type to use. Image or Movie uses pixel based material that you have to load externally. The rest are procedural computer generated textures. Some of them are based at different noise algorithms.

Each texture type has its own settings which will be described below.

## Preview panel

A preview window for the texture.

## Blend panel

Image Type Blend.

## Progression

The style of the color blending.

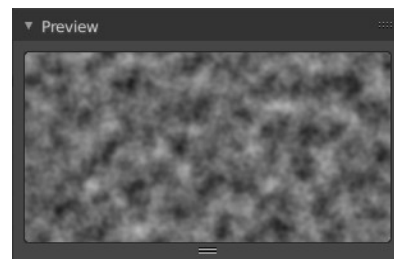

## Orientation

The direction. Horizontal or vertical.

# Clouds panel

Image type clouds

## Noise Basis

What noise method to use.

## Type

Smooth transitions or sharp transitions. Changes contrast and sharpness.

## Color

### Grayscale

Grayscale based noise. The value returned is greyscale 8 bit.

### Color

The noise gives an RGB value. The value returned is rgb 24 bit.

## Size

The dimension of the Noise table.

## Depth

The depth of the Clouds calculation. A higher number results in a long calculation time, but also in finer details.

## Nabla

Size of derivate offset used for calculating normal.

In order to calculate a normal, you usually use three samples in texture space. Typically that's the current

sample location, and two other positions in texture U and V directions. This "nabla" value defines how far away these positions are.

## Distorted Noise panel

Image type Distorted Noise

### Noise Basis

What noise method to use.

### Distortion

What noise method to use for the distortion.

### Amount

The amount of distortion.

### Size

The dimension of the Noise table.

### Nabla

Size of derivate offset used for calculating normal.

In order to calculate a normal, you usually use three samples in texture space. Typically that's the current sample location, and two other positions in texture U and V directions. This "nabla" value defines how far away these positions are.

## Image panel - Settings Subpanel

Image type Image or Movie.

## Image Property

Load an image and / or switch to other images.

## Texture browser

A texture browser with the available textures.

## Edit Box

The name of the currently active palette. You can also rename the palette here. A click into the edit box makes the name editable.

## Unlink Data-Block

Remove the texture.

---

## File selector menu

## **New**

Create a new image.

Creates a new image. You will get a dialog where you can define settings for the new image.

## **Name**

The name of the new image

## **Width**

The width of the new image.

## **Height**

The height of the new image.

## **Color**

Adjust the color of the new image. A click will call a color picker.

## **Alpha**

Check this checkbox if the new image should have an alpha channel.

## **Generated Type**

Here you can define what kind of texture you want to create.

Blank is one plain color.

UV Grid is a checker texture in black and white.

Color Grid is a colored checker texture.

## **32 Bit Float**

Check this checkbox if the image should be in 32 Bit floating point bit depth per channel. Else it is in 8 bit per channel.

## **Duplicate**

Not supported here.

## **Unlink Datablock**

This deletes the selected image. Unfortunately not immediately. You need to save the scene and to reload it.

And you need to make sure that it is not linked to anything else. A mesh or a fake user for example. Have a look if there is a number besides the F button. When this is the case then the image has still a user, and so still loads with loading the scene.

## **Fake User**

With this button you assign a fake user to this selected image.

Data, like images, that is not longer linked to anything else gets removed when you save and reload a scene. Bforartists has the concept of fake users to go around this behavior. An image with a fake user is in fact linked to something. And so it is not lost when you save and reload the scene.

### ***Open Image***

Opens the file browser to load an image.

### ***Unpack***

Unpack packed files to a directory.

### ***User***

The number of users that uses this data. Data with a user number of 0 will be removed with closing Bforartists.

---

## **Source**

Choose the image type. This type gets usually automatically set. When you create a new image, then this image is generated. When you load an image then the Source switches to Single Image.

Generated images does not have a path.

---

## **Source Type Generated**

### ***X / Y***

The image width and height.

### ***Float Buffer***

Use a floating point buffer. 8 Bit images uses integers. 32 Bit works with floats.

---

## **Generated Type Blank**

This type displays an image with one blank color

### **Color**

The color of the blank image.

## **Generated Type UV Grid**

This type displays a with a black and white checker texture but colored dots.

### Generated Type Color Grid

This type displays a with a colored checker texture with numbers.

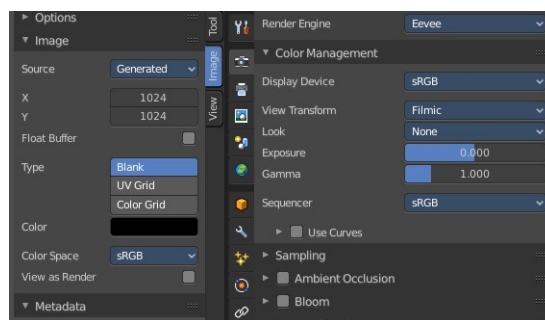

### Color Space

Choose the color space type for the image.

### View as Render

Displays the image with the color management settings.

### Source Type Movie + Image Sequence

### Path edit box

### Pack

With this button you can pack the movie or the image sequence into the blend file. It gets packed when you

save the blend file the next time.

### **Path edit box**

See and edit the path to your movie or image sequence files.

### **Open**

Open a new movie or image sequence files. A file dialog will appear.

### **Refresh**

Reread the movie or image sequence files.

---

## ***Info string***

Some information about the currently loaded movie. Frames, resolution and color space.

---

## ***Frames***

The number of frames of the movie or image sequence.

## **Match Movie Length**

Set Users Image Length to the one of this video.

## ***Start***

The start frame of the movie or image sequence

## ***Offset***

Offset the number of the frame to use in the animation. -1 means off.

## ***Cyclic***

Cycle the images in the movie.

## ***Auto Refresh***

Always refresh image on frame changes.

## ***Deinterlace***

Deinterlace the movie file on load.

---

## ***Color Space***

Choose the color space type for the movie or image sequence files.

## Alpha

Choose the alpha channel mode. Straight or Premultiplied.

## View as Render

Display the image with using the color management settings.

## Source Type Single Image

### Path edit box

### Pack

With this button you can pack the movie or the image sequence into the blend file. It gets packed when you save the blend file the next time.

### Path edit box

See and edit the path to your movie or image sequence files.

### Open

Open a new movie or image sequence files. A file dialog will appear.

### Refresh

Reread the movie or image sequence files.

## Info string

Some information about the currently loaded image. Resolution and color space.

## Color Space

Choose the color space type for the movie or image sequence files.

## Alpha

Choose the alpha channel mode. Straight or Premultiplied.

## View as Render

Display the image with using the color management settings.

## Source Type Udim

UDIM is an enhancement to the UV mapping and texturing workflow. And does not belong here. But in the UV Editor. It is just in the list because it shares the same menus with the UV Editor.

## Image panel - Alpha Subpanel

Use the Alpha channel that is stored in the image.

### Calculate

Calculate an alpha based on the RGB values of the Image. Black (0, 0, 0) is transparent, white (1, 1, 1) opaque.

Enable this option if the image texture is a mask. Note that mask images can use shades of gray that result in semi-transparency, like ghosts, flames, and smoke/fog.

### Invert

Reverses the alpha value. Use this option if the mask image has white where you want it transparent and vice versa.

## Image panel - Mapping Subpanel

Control how the image is mapped or projected onto the 3D model.

### Flip Axes

Rotates the image 90 degrees counterclockwise when rendered.

### Extension

#### Extend

Outside the image the colors of the edges are extended.

## Clip

Clip to image size and set exterior pixels as transparent. Outside the image, an alpha value of 0.0 is returned. This allows you to 'paste' a small logo on a large object.

## Clip Cube

Clips to cubic-shaped area around the images and sets exterior pixels as transparent. The same as Clip, but now the 'Z' coordinate is calculated as well. An alpha value of 0.0 is returned outside a cube-shaped area around the image.

## Repeat

The image is repeated horizontally and vertically.

### **Repeat X / Y**

X/Y repetition multiplier.

### **Mirror X / Y**

Mirror on X/Y axes. These buttons allow you to map the texture as a mirror, or automatic flip of the image, in the corresponding X and/or Y direction. They become active when the Repeat value is higher than 1.

## Checker

Checkerboards quickly made. You can use the option size on the Mapping panel as well to create the desired number of checkers.

### **Distance**

Governs the distance between the checkers in parts of the texture size.

### **Tiles Even / Odd**

Set even/odd tiles.

## Crop Sub tab

### **Crop Minimum X / Y + Crop Maximum X / Y**

The offset and the size of the texture in relation to the texture space. Pixels outside this space are ignored. Use these to crop, or choose a portion of a larger image to use as the texture.

## Image panel - Sampling Subpanel

## Interpolation

Interpolate pixels using selected filter type.

## MIP Map

Use auto generated MIP maps.

## Gaussian Filter

Use Gauss filter to sample down the mip map images.

## Filter Type

The texture filter to use for sampling images.

### Type Box

#### Size

Multiply the filter size used by MIP map and interpolation.

### Type EWA

#### Eccentricity

Maximum eccentricity. Higher values gives less blur at distance angles and is slower.

#### Size

Multiply the filter size used by MIP map and interpolation.

### Type FELINE

#### Light Probes

Maximum number of samples. Higher values gives less blur at distance angles and is slower.

#### Size

Multiply the filter size used by MIP map and interpolation.

### Type Area

#### Eccentricity

Maximum eccentricity. Higher values gives less blur at distance angles and is slower.

#### Size

Multiply the filter size used by MIP map and interpolation.

## Minimum Size

Use the filter size as a minimal filter value.

## Magic panel

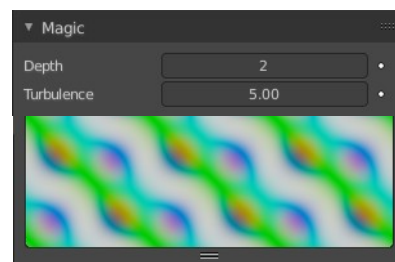

Image type Magic.

### Depth

The depth of the calculation. A higher number results in a long calculation time, but also in finer details.

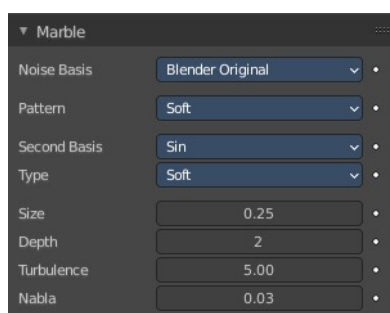

### Turbulence

The strength of the pattern.

## Marble panel

Image type Marble.

### Noise Basis

What noise method to use.

### Pattern

Settings for soft to more clearly defined Marble.

### Second basis

Shape of wave to produce bands.

### Type

The noise function works with two methods. Soft or hard.

### Size

The dimensions of the noise table.

## Depth

The depth of the Marble calculation. A higher value results in greater calculation time, but also in finer details.

## Turbulence

The turbulence of the sine bands.

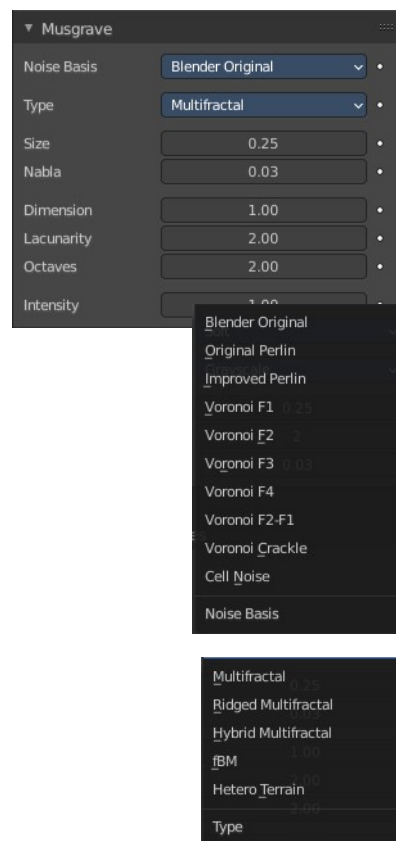

## Nabla

Size of derivate offset used for calculating normal.

In order to calculate a normal, you usually use three samples in texture space. Typically that's the current sample location, and two other positions in texture U and V directions. This "nabla" value defines how far away these positions are.

# Musgrave panel

Image type Musgrave.

## Noise Basis

What noise method to use.

## Type

What noise type to use.

## Size

The input noise scale.

## Nabla

Size of derivate offset used for calculating normal.

In order to calculate a normal, you usually use three samples in texture space. Typically that's the current sample location, and two other positions in texture U and V directions. This "nabla" value defines how far away these positions are.

## Dimension

Fractal dimension controls the contrast of a layer relative to the previous layer in the texture. The higher the fractal dimension, the higher the contrast between each layer, and thus the more detail shows in the texture.

## Lacunarity

Lacunarity controls the scaling of each layer of the Musgrave texture, meaning that each additional layer will have a scale that is the inverse of the value which shows on the button. i.e. Lacunarity = 2 → Scale = 1/2 original.

## Octaves

Octave controls the number of times the original noise pattern is overlaid on itself and scaled/contrasted with the fractal dimension and lacunarity settings.

## Intensity

Light intensity. Called Offset for Hetero Terrain.

## Offset

Hybrid Multifractal and Ridged Multifractal type. Both have a “Fractal Offset” button that serves as a “sea level” adjustment and indicates the base height of the resulting bump map. Bump values below this threshold will be returned as zero.

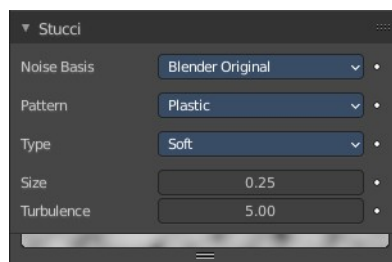

## Gain

Hybrid Multifractal and Ridged Multifractal type. Setting which determines the range of values created by the function. The higher the number, the greater the range. This is a fast way to bring out additional details in a texture where extremes are normally clipped off.

## Stucci panel

Image type Stucci.

## Noise Basis

What noise method to use.

## Pattern

Plastic is the standard Stucci, while the “walls” is where Stucci gets its name. This is a typical wall structure with holes or bumps.

## Type

There are two methods available for working with Noise. Soft or Hard.

## Size

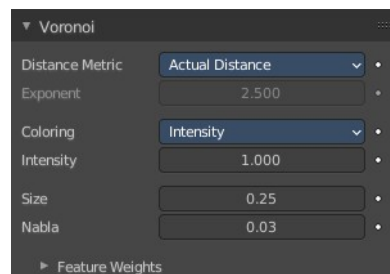

Dimension of the Noise table.

## Turbulence

Depth of the Stucci calculations.

# Voronoi panel

Image type Voronoi.

## Distance Metric

This procedural texture has seven Distance Metric options. These determine the algorithm to find the distance between cells of the texture.

## Exponent

The Minkowski setting has a user definable value (the Exponent button) which determines the Minkowski exponent  $e$  of the distance function.

$$(xe + ye + ze)^{1/e}$$

A value of one produces the Manhattan distance metric, a value less than one produces stars (at 0.5, it gives a Minkowski 1/2), and higher values produce square cells (at 4.0, it gives a Minkowski 4, at 10.0, a Chebychev). So nearly all Distance Settings are basically the same – a variation of Minkowski.

## Coloring

Different ways to calculate color and intensity of the texture output.

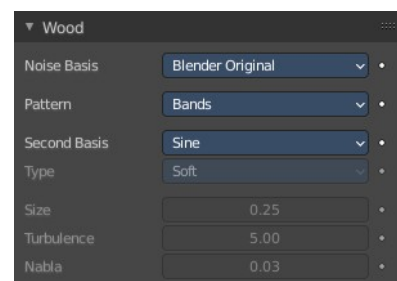

## Feature Weights subpanel

These four sliders at the bottom of the Voronoi panel represent the values of the four Worley constants, which are used to calculate the distances between each cell in the texture based on the distance metric.

# Wood panel

Image type Wood.

## Noise Basis

What noise method to use.

## Pattern

The wood pattern.

Type, Size Turbulence and Nabla are just active with Pattern Type Band Noise and Ring Noise.

## Second basis

Shape of wave to produce bands.

## Type

Smooth transitions or sharp transitions. Changes contrast and sharpness.

## Turbulence

The turbulence of band noise and ring noise.

## Nabla

Size of derivate offset used for calculating normal.

In order to calculate a normal, you usually use three samples in texture space. Typically that's the current sample location, and two other positions in texture U and V directions. This "nabla" value defines how far away these positions are.

## Colors Panel

### Clamp

Clamps the range by setting the negative rgb and intensity values to zero.

### Multiply R G B

Multiply factor for the r g and b channel.

### Brightness

The brightness of the texture.

### Contrast

The contrast of the texture.

### Saturation

The saturation of the texture.

### Color ramp subpanel

Specify a range of colors based on color stops. The color between the color stops gets interpolated.

+

Add a stop to your color ramp. The stop will be added after the selected one, in the middle to the next one.

-

Deletes the selected color stop from the list.

### Tools menu

#### *Flip Color Ramp*

Flips the gradient, inverting the values of the color ramp.

### ***Distribute Stops from Left***

Rearrange the stops so that every step has the same space to the right.

### ***Distribute Stops Evenly***

Space between all neighboring stops becomes equal.

### ***Eyedropper (pipette icon) E***

An Eyedropper to sample a color or gradient from the interface to be used in the color ramp.

### ***Reset Color Ramp***

Resets the color ramp to its default state.

## **Color Mode**

### ***RGB***

Blends color by mixing each color channel and combining.

### ***HSV/HSL***

Blends colors by first converting to HSV or HSL, mixing, then combining again. This has the advantage of maintaining saturation between different hues, where RGB would de-saturate, this allows for a richer gradient.

## **Interpolation**

### ***Ease***

Uses an Ease Interpolation for the color stops.

### ***Cardinal***

Uses a Cardinal Interpolation for the color stops.

### ***Linear***

Uses a Linear Interpolation for the color stops.

### ***B-Spline***

Uses a B-Spline Interpolation for the color stops.

### ***Constant***

Uses a Constant Interpolation for the color stops.

## **Color Ramp**

The color band. A click at one of the color stops makes it the active one. You can move the color stops by clicking at them and dragging them around.

## Active Color Stop elements

Adjust the active color stop.

### Choose active color stop

Choose the color stop by index.

### Pos

The position of the active color stop. The range goes from 0.000 to 1.000

### Color

The color of the active color stop. Clicking at it opens a color picker.

## Custom Properties Panel

Allows to define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

### Add

Adds a new property.

### Edit

Opens a panel where you can adjust the settings for the custom property.

### Remove

Removes the property.

## Editors - Properties Editor - Bone Tab

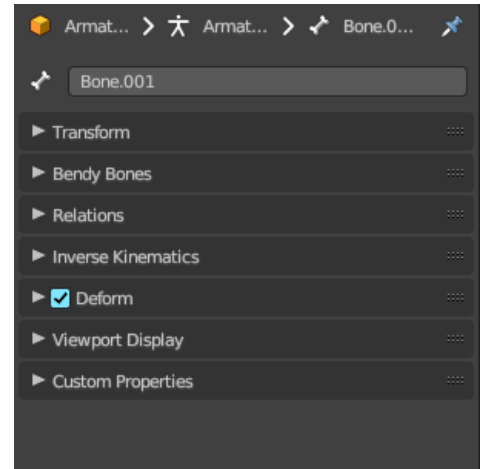

The bone tab contains bone related settings. The content differs from mode to mode.

**Object Mode**

**Edit Mode**

**Pose Mode**

## Transform panel

### Edit Mode

In Edit mode the bones are created and modified. A bone has a head and a tail. These positions can be adjusted.

### Head X, Y Z

The position of the head of the selected bone.

### Tail X, Y Z

The position of the head of the selected bone.

### Roll

The bone rotation around the head - tail axis.

### Lock

Lock the whole bone, the head or the tail from further editing. This depends of what is the current active element.

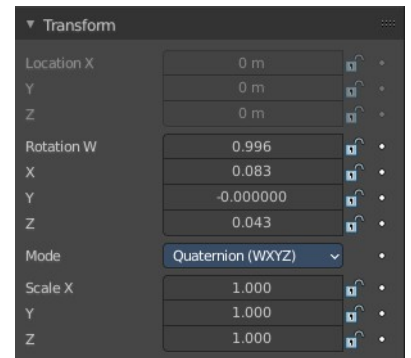

## Pose Mode

### Location X Y Z

The location of the root bone. Just the root bone can be re-positioned. For all other bones in the hierarchy the edit boxes are greyed out.

### Rotation W X Y Z

The rotation of the current bone. With Mode Quaternion you will have the W axis too. With euler angles you will just have X Y and Z axis.

### Mode

The rotation mode to use. Euler angles can run into a gimbal lock problem. This means the bone is not longer rotatable. Quaternion rotation avoids gimbal lock.

### Scale X Y Z

The scale of the bone.

## Bendy Bones panel

Settings for bendy bones. Bendy bones, also called Bbone, is a special bone mode that allows to divide bones into segments that can be bend and rotated. The “BBone Shape” Keying Set includes all Bendy Bones properties.

You have to activate Bbone in the Object data in the Viewport Display panel. Display as.

The settings becomes activated when the number of segments is higher than 1.

### Segments

The Segments number field allows you to set the number of segments, which the given bone is subdivided into. Segments are small, rigid linked child bones that interpolate between the root and the tip. The higher this setting, the smoother “bends” the bone, but the heavier the pose calculations.

### Curve X Y Offsets

Applies offsets to the curve handle positions on the plane perpendicular to the bone’s primary (Y) axis. As a result, the handle moves per axis (XY) further from its original location, causing the curve to bend.

### Roll

Roll In, Out

The roll value (or twisting around the main Y axis of the bone) is interpolated per segment, between the start and end roll values. It is applied as a rotational offset on top of the previous rotation.

### Inherit End Roll

If enabled, the Roll Out value of the Start Handle bone (connected parent by default) will be implicitly added to the Roll In setting of the current bone.

### Scale

Scale In X/Y, Scale Out X/Y

Scaling factor that adjusts the thickness of each segment for the X and Y axes only, i.e. length (Z axis) is not affected. Similar to Roll it is interpolated per segment.

## Ease In , Ease Out

The Ease In/Out number fields, change the “length” of the “auto” Bezier handle to control the “root handle” and “tip handle” of the bone, respectively.

These values are proportional to the default length, which of course automatically varies depending on bone length, angle with the reference handle, and so on.

## Scale Easing

Multiply the final easing values by the Scale In and Out Y value.

## Custom Handles

B-Bones can use custom bones as their reference bone handles, instead of only using the connected parent/child bones.

## Start + End Handle Type

Specifies the type of the handle from the following choices:

### Automatic

The connected parent (or first connected child) of the bone is chosen as the handle. Calculations are done according to the Absolute handle type below.

### Absolute

The Bezier handle is controlled by the position of the head (tail) of the handle bone relative to the head (tail) of the current bone. If the handle is also a B-Bone, additional processing is applied to further smooth the transition, assuming that the bones in effect form a chain.

### Relative

The Bezier handle is controlled by the offset of the head (tail) of the handle bone from its rest pose. The use of this type is not recommended due to numerical stability issues near zero offset.

### Tangent

The Bezier handle is controlled by the orientation of the handle bone, independent of its location.

### Custom Handle

For types other than Automatic, a bone to use as handle has to be manually selected. Switching to a custom handle type without selecting a bone can be used to effectively disable the handle.

It is valid for two bones to refer to each other as handles – this correlation is applied in connected chains with Automatic handles.

### Scale

Multiply the B Bone scale out channels by the local scale values of the start or end handle in x, y or z direction.

## Ease

Use easing for the scaling, not linear.

# Relations panel

Relation related settings. Note that in Edit mode relative parenting does not display.

## Parent

Usually bones are in a hierarchy with parent and child bones. This parent edit box displays the parent bone. The parent bone can be edited in edit mode.

## Relative Parenting

Object children will use relative transform. Like deform.

## Connected

Set the head of the bone to be connected with its parent root.

## Local Location

When disabled, the location transform property is evaluated in the parent bone’s local space, rather than using the bone’s own rest pose local space orientation.

## Inherit Rotation

When disabled, this will “break” the rotation relationship to the bone’s parent. This means that the child will keep its rotation in the armature object space when its parent is rotated.

## Inherit Scale

Specifies which effects of parent scaling the bone inherits.

### Full

The bone inherits all effects of parent scaling and shear.

### Fix Shear

Corrects the transformation inherited from the parent to remove shear caused by non-uniform parent scaling and rotation. The process preserves the bone direction, length and volume, and minimally affects roll on average.

If the inherited scale is non-uniform, this does not prevent shear from reappearing due to local rotation of the child bone, or of its children.

## Aligned

Parent scaling is inherited as if the child was oriented the same as the parent, always applying parent X scale over child X scale, and so on.

This mode never causes shear and is natural for connected chains like limbs and tentacles.

## Average

Inherits a uniform scaling factor that is the total change in the volume of the parent.

This effectively keeps the uniform part of the scaling of the parent, while removing squash and stretch effects. Uniform scaling never causes shear.

## None

Ignores all scaling and shear of the parent.

## None (Legacy)

Ignores all scaling, provided the parent is not sheared. If it is, there are no guarantees.

This choice replicates the behavior of the old Inherit Scale checkbox, and may be removed in a future release.

These inheriting behaviors propagate along the bones' hierarchy. So when you scale down a bone, all its descendants are by default scaled down accordingly. However, if you disable one bone's Inherit Scale or Inherit Rotation property in this "family", this will break the scaling propagation, i.e. this bone and all its descendants will no longer be affected when you scale one of its ancestors.

## Bone Collections subpanel

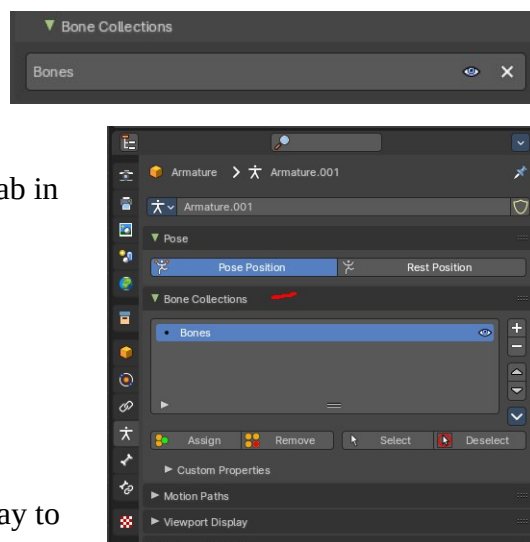

Bones can be organized and can exist in different collections. Here you can see and to some degree manage them. Creating the collections is not possible from here. This must be done in the data tab in the Bone Collection panel.

## Visible

Make the collection visible or invisible.

## Remove

Removes the bone from the bone collection. Attention, there is no way to add this bone back then. The remove functionality just works in edit and pose mode.

## Deform panel

### Deform

Enable the bone to deform geometry.

Toggling the checkbox in the panel header off, prevents the bone from deforming the geometry at all, overriding any weights that it might have been assigned before; It mutes its influence.

It also excludes the active bone in the automatic weight calculation when the mesh is parented to the armature using the Armature Deform tool with the “With Automatic Weights” option.

### Envelope Distance

Envelope is something like a hull around the bone, which defines an influence area for weighting.

The Distance defines a volume which is the range within the bone has an influence on vertices of the deformed object. The geometry is less and less affected by the bone as it goes away by following a quadratic decay.

### Envelope Weight

A bone property, that controls the global influence of the bone over the deformed object, when using the envelopes method.

It is only useful for the parts of geometry that are “shared”, influenced by more than one bone (generally, at the joints...) – a bone with a high weight will have more influence on the result than one with a low weight... Note that when set to 0.0, it has the same effect as disabling the Deform option.

### Envelope Multiply

When deforming bone, multiply effects of vertex group weights with Envelope influence.

### Radius Head

Set the radius for the head of envelope bones. Inside this volume, the geometry is fully affected by the bone.

### Tail

Set the radius for the tail of envelope bones. Inside this volume, the geometry is fully affected by the bone.

## Inverse Kinematics panel

Settings for inverse kinematics. This is for Pose mode only.

### IK stretch

Allow scaling of the bone for IK.

### Lock IK X Y Z

Lock the single axis for IK.

### Stiffness X Y Z

Add a stiffness around the axis.

### Limit X

Limit movement around the X axis.

### Limit Y

Limit movement around the X axis.

### Limit Z

Limit movement around the X axis.

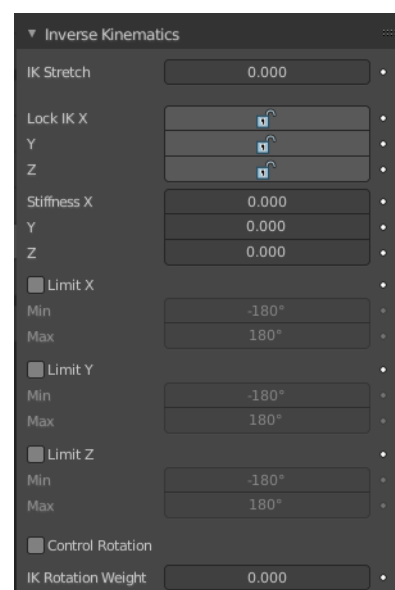

### Control Rotation

When you use Inverse Kinematics with the iTaSC solver in the object data properties in the Inverse Kinematics panel, then you will reveal this checkbox.

Apply channel rotation as IK constraint.

### IK Rotation Weight

Weight of rotation constraint for IK.

## Viewport Display panel

This panel controls the viewport display settings of each bone.

**Note:** To apply settings to all bones, hold down ALT before selecting or toggling.

## Hide

Hides the selected bone in the viewport. This toggle is mode dependant. So it is possible for example to hide the bone in edit mode, but keep in pose and object mode.

## Bone Color

Use a color theme for your bone group.

## Bone Color Set

A set of predefined bone color sets for Edit Mode. Each set is made of three colors.

### Normal

The first color field is the color of unselected bones.

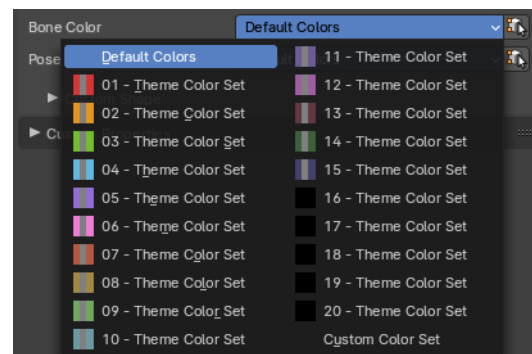

### Selected

The second color field is the outline color of selected bones.

### Active

The third color field is the outline color of the active bone.

The custom color set is editable. The other color sets are fixed.

## Copy Colors to Selected

Pose mode only. Copy the bone color of the active bone to all selected bones.

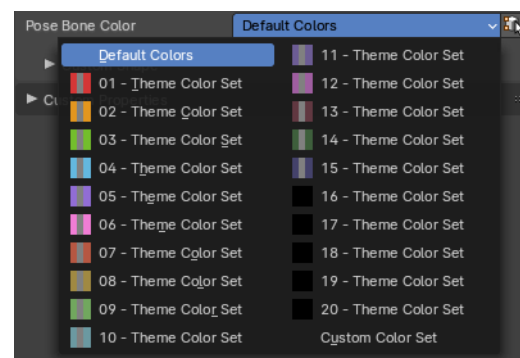

## Pose Bone Color

A set of predefined bone color sets for Pose Mode. Like in the Edit Bone Colors, each set is made of three colours based on a normal colour, selected and active.

**Note:** You can change pose bone colour in Pose Mode too.

## Sync to Selected

Pose mode. Copy the bone color of the active bone to all selected bones.

## Custom Shape

Use a custom object to be displayed as the bone in Object and Pose mode.

### Workflow

Switch to Pose Mode.

Select the relevant bone by clicking on it.

Go to the Display panel Custom Shape field and select an object in the scene that you want to use as a display object.

### Custom Object

The object that defines the custom shape of the selected bone.

### Override Transform

Bone that defines the display transform of the custom shape.

### Scale

Scale the custom object.

### Translation

Position the custom object.

### Rotation

Rotate the custom object. This happens in Euler angles.

### Override Transform

The bone that defines the display transform of this custom shape.

### Scale to Bone Length

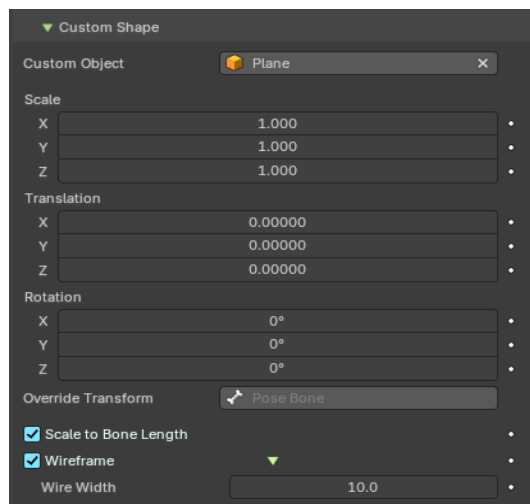

Option not to use bones length, so that changes in Edit Mode don't resize the custom shape.

### Wireframe

Display wireframe on bones regardless of viewport shading mode.

### Wire width

The width of the wireframe of the custom shape.

## Bone Constraints

Constraints allows two objects to interact with each other. You can for example set the x position to the x position of another object with the Copy Location constraint. Bone constraints is a special constraints chapter just dedicated to bones. And just shows when you have an armature or a bone selected.

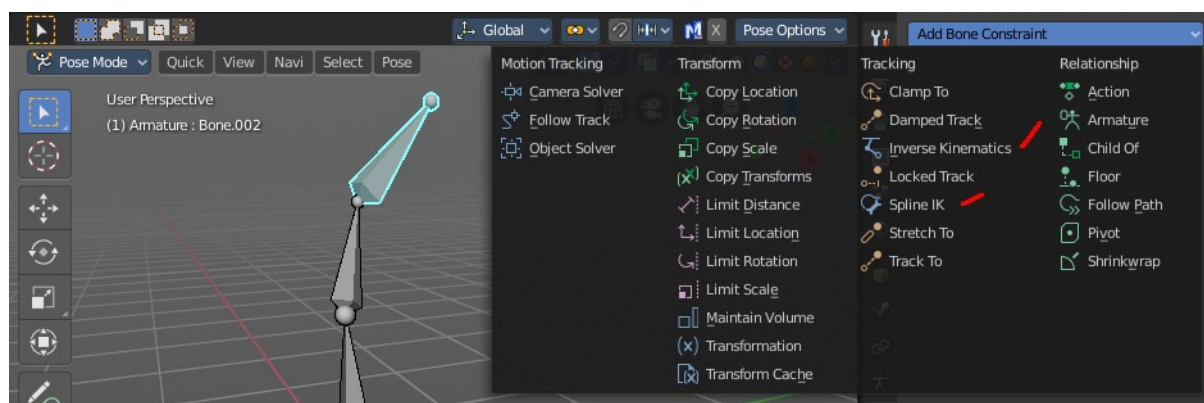

Bones behave like objects in Pose Mode. And so they can also be constrained.

The Bone Constraints tab shows in Object Mode and Pose mode.

In Object mode you can edit existing constraints. But you can't add constraints in Object mode. Bone Constraints can only be added in Pose Mode.

The constraints drop down menu shows the same constraints than the Object Constraints tab. You can add any of the other object constraints here. Like a Limit Rotation from the Transform category, to limit the rotation of an elbow for example.

Most of the other constraints works with all object types, and are explained in the Object Constraints chapter. But there are two constraints that just works for and with bones. And can just be added from the Bone Constraints drop down menu. The IK constraint and the Spline IK constraint. Both are covered in this chapter.

## What is Inverse Kinematics?

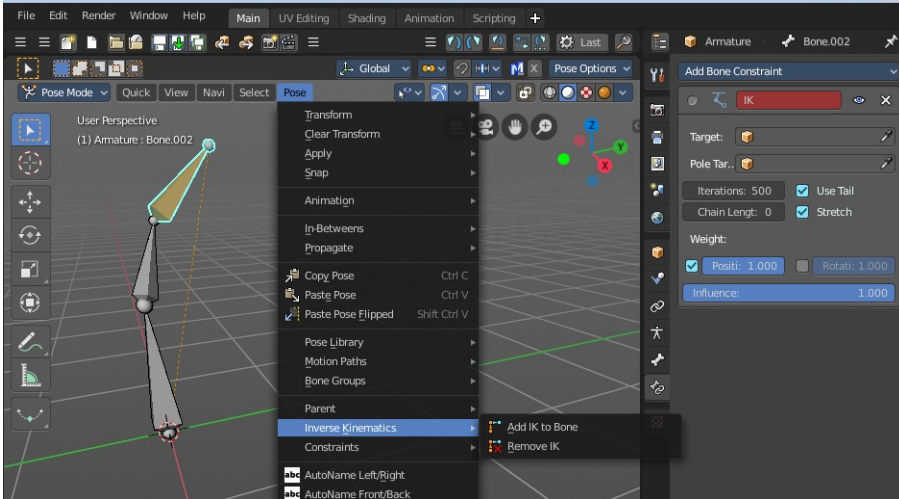

You can pose a skeleton in two ways. With Forward Kinematics. And with Inverse Kinematics.

Forward kinematics means, you bend a bone, and the bones downwards the hierarchy follows this motion. For example you pull the elbow, and the hand with its fingers follows. You don't need a constraint for that. This is native behavior of an armature.

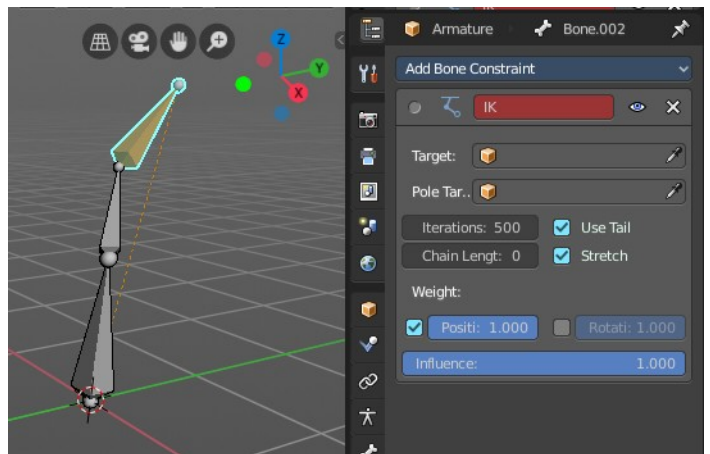

The other technique is called inverse kinematics. Here the motion gets calculated upwards the hierarchy. For example you pull at the hand, and the arm follows. That's where you need the IK Constraint.

## Quick Setup

You can add the Inverse Kinematics from the 3D View. Or directly in the Bone Constraints panel. In Pose Mode select the bone, and either choose the Add IK to Bone in the Pose menu. Or add the constraint directly in the Bone Constraint tab.

The Add IK to Bone menu item brings up a sub item. Without targets means that it just creates the constraint. It misses the handler to pose it then. And so you have to pull at the bone with the IK solution to pose your armature. The title of the constraint is red when the target is missing. Which usually means that the constraint is dysfunctional since it misses some vital information. But you can nevertheless use this constraint in Pose Mode as is.

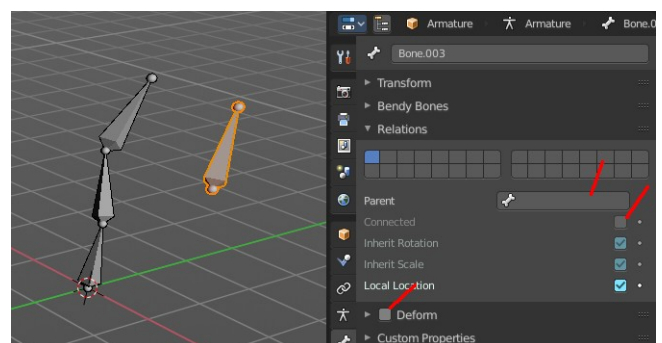

A common method is to use an unconnected Bone inside of the same armature to be the target or the pole target. But then you can still just pose this armature in Pose mode.

## Adding a bone as an IK handler

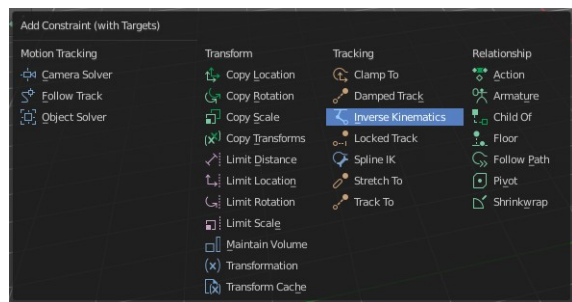

In Edit Mode create a loose bone in your armature. Turn off Connected and clear Parent in the Relations panel.

Untick Deform. We use this bone as a handler, not as a bone.

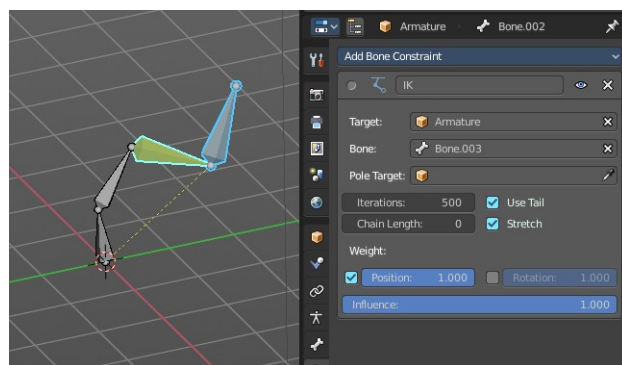

Go to Pose mode. Select the IK bone. Hold down Shift and select the bone where you want to add the IK to.

Then in the Pose menu choose Constraints, Add (With Targets), and choose the IK constraint in the upcoming menu.

This creates the IK constraint, and will add our prepared bone to be the target. And now you can pull at this bone in Pose Mode, and the IK solution will follow this bone.

Needless to say that you might be faster to add the IK constraint manually in the Bone IK tab here. You have to adjust it anyways ...

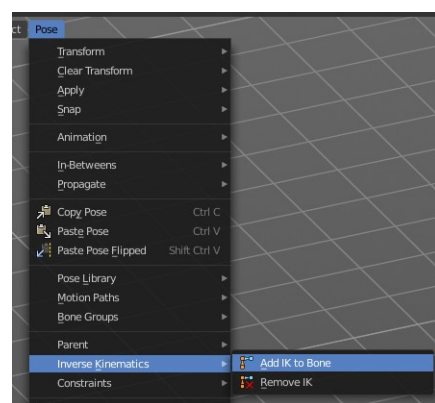

## Adding an Object as an IK handler

You might want to animate a character together with other objects. They are usually animated in Object Mode. And so you need a solution to pose your character in Object mode, and not in Pose mode. For that you can simply add any object in the scene to be the IK handler instead of a bone in the same armature.

First go to the Pose menu again. Choose Inverse Kinematics / Add IK to Bone. Then choose To New Empty Object

This adds the IK constraint, and creates an empty as the Target. This empty can then be used as a handler to pose the IK solution in Object Mode. The IK solution will follow this Target.

You can add any other object in the scene as a Target. It does not need to be an empty. Simply replace it in the IK constraint in the Target edit box.

The further functionality of the IK constraint gets explained below.

## IK Constraint

### Target

Add an object as an IK handler object.

### Bone

If the target is an armature, then you can choose the bone here that you want to use as an IK handler.

### Pole Target

Add an object to be the Pole target.

Pole target is a secondary IK target. An object that lets the IK solution point into a defined direction, towards this object.

Think of a knee here for example. Without a Pole target the knee might dance around when you try to pose the leg. And it will point in all directions but the one in that it should bend. With a Pole target you can let the IK solution point towards this target object.

### Bone

If the target is an armature, then you can choose the bone here that you want to use as a Pole Target.

### Pole Angle

The IK solution might not point correctly into the direction of the Pole target. Or you might need some offset. This property allows you define an offset for the pole angle.

### Iterations

The maximum number of iterations to calculate the IK solution

## Chain Length

How many bones are included into this IK solution. A value of 0 uses all bones.

## Use Tail

Include the Bone's tail as the last element in chain.

## Stretch

Enable IK stretching.

## Weight

## Position

For Tree IK (multiple IK targets): Weight of Position Control for this target.

## Rotation

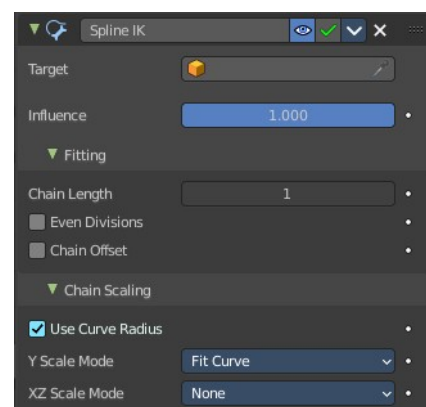

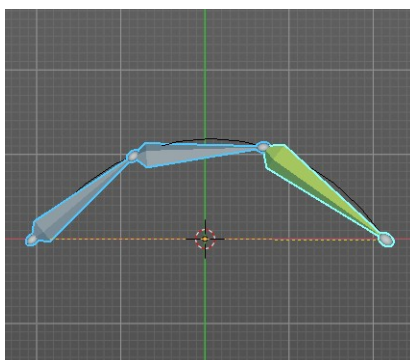

For Tree IK (multiple IK targets): Weight of Orientation Control for this target.

## Influence

The influence level of this constraints.

## Spine IK Constraint

The *Spline IK* constraint aligns a chain of bones along a curve. This constraint requires to have a curve object in the scene as the target object. So you should create one beforehand.

## Target

Choose the target curve.

## Influence

The influence level of this constraints.

## Fitting subpanel

### Chain Length

How many bones are included in the chain. Set it to 0 to influence the whole chain.

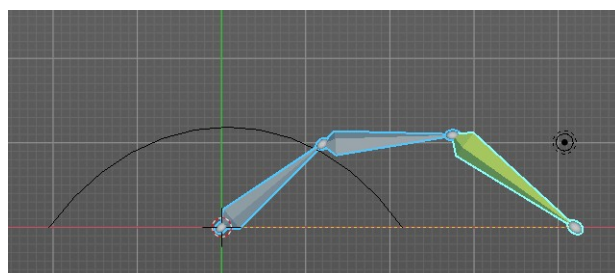

### Even Division

Ignore the relative length of the bones when fitting to the curve. Every bone in the chain will be equal long.

### Chain Offset

Offset the entire chain relative to the root joint. Else just the bones in reach of the chain length gets aligned.

Note: The calculation happens relative to the curve. When this curve is rotated in world space, then the bones still uses the unrotated state of the curve.

## Chain Scaling subpanel

### Use Curve Radius

Average radius of the endpoints is used to tweak the X and Z scaling of the bones, on top of the X and Z scale mode.

### Y scale mode

Choose how the bone length should fit into the curve length.

#### **None**

Don't scale the X and Z axes.

#### **Fit Curve**

Fit the bone chain length into the length of the curve.

#### **Bone Original**

Use the original scaling of the bones.

## XZ Scale Mode:

### **None**

Don't scale the X and Z axes.

### **Bone Original**

Use the original scaling of the bones.

---

### **Inverse Scale**

Scale of the Z and X axis is the inverse of the Y axis.

### **Use Original Scale**

Apply volume preservation over the original scaling.

---

### **Volume Preservation**

Scale of the X and Z axes is the inverse of the Y scale. With enabling Volume Preservation you will reveal some further options for this method.

### **Use Original Scale**

Apply volume preservation over the original scaling.

### **Volume Variation**

Factor between volume variation and stretching.

### **Volume Min / Volume Max**

Minimum and maximum volume stretching factor.

### **Smooth**

You need to have either Volume min or Volume max set to active to show this setting. Adjust the factor between volume variation and stretching.

## Render Tab

There are three different render engines available. Workbench, Eevee, and Cycles. This chapter has a focus on the Eevee render engine.

Cycles is a so called offline renderer. It is an unbiased physically correct renderer with some biased adjustments to make it usable for animations.

Cycles can render at the CPU or the GPU.

## Cycles Feature Set

When you choose Cycles then you will see a new drop down box called Feature set. Cycles has two feature set settings. Supported and Experimental.

Supported means you have all common Cycles settings available.

Experimental means that you have access to some further experimental features of Cycles, which are somehow functional, but are still experimental features. Like Adaptive subdivision. Those features may or may not work proper. Use at own risk!

## Cycles Device

When you turn on Cuda in the User Preferences then you will get a Device drop down box to choose if you want to render with the CPU or the GPU.

## Open Shading Language

When you render with Cycles at the CPU, then you can choose to use the Open Shading Language.

## Sampling panel

Adjust the samples for Cycles. And enable denoising.

## Viewport subpanel

Sampling settings for the Viewport rendering.

## Presets

In the header you will find a Presets menu to choose between presets and define your own presets.

## Adaptive Sampling

Automatically reduce the number of samples per pixel, based on estimated noise level.

### *Adaptive sampling threshold*

The noise level step to stop sampling at. Lower values reduces noise at the cost of render time. A value of zero means to use the automatic setting based on number of AA samples.

### *Max Samples*

Maximum samples for adaptive sampling.

### *Min Samples*

Minimum samples for adaptive sampling. A value of zero means to use the automatic setting based on number of AA samples.

## Samples

When Noise Threshold is off then you will see the Samples edit box. Number of samples to render.

## Denoise Sub Subpanel

### *Use Denoising Checkbox*

Activate Denoising.

## ***Denoiser***

### **Automatic**

Use the fastest denoiser that is available. If OptiX is available then OptiX. Otherwise OpenImageDenoiser.

### **OptiX**

Use the OptiX Denoiser.

### **OpenImageDenoiser**

Use the OpenImageDenoiser.

## ***Passes***

What input passes to use.

## ***Start Sample***

The sample to start denoising at.

---

## **Render subpanel**

Sampling settings for the final rendering.

## **Presets**

In the header you will find a Presets menu to choose between presets and define your own presets.

## **Adaptive Sampling**

Automatically reduce the number of samples per pixel, based on estimated noise level.

### ***Adaptive sampling threshold***

The noise level step to stop sampling at. Lower values reduces noise at the cost of render time. A value of zero means to use the automatic setting based on number of AA samples.

### ***Max Samples***

Maximum samples for adaptive sampling.

### ***Min Samples***

Minimum samples for adaptive sampling. A value of zero means to use the automatic setting based on number of AA samples.

## Samples

When Noise Threshold is off then you will see the Samples edit box. Number of samples to render.

## Time Limit

When Noise Threshold is off then you will see the Time Limit edit box. Limit the render time. This ends the rendering process after the given time. A value of zero disables the limit.

## Denoise Sub Subpanel

### Use Denoising Checkbox

Activate Denoising.

### Denoiser

### OptiX

Use the OptiX Denoiser.

### Passes

What input passes to use.

### OpenImageDenoiser

Use the OpenImageDenoiser.

### Passes

What input passes to use.

### Prefilter

Prefilter noisy guiding to improve quality.

### Quality

Overall denoising quality.

### Use GPU

Perform Denoising on the GPU.

This property is just active when Cycles device uses GPU and the denoiser is OpenImage Denoise.

## Path Guiding subpanel

Use path guiding for sampling paths. Path guiding incrementally learns the light distribution of the scene. And guides path into directions with high direct and indirect light contributions.

### Training Samples

The maximum number of samples used for training path guiding. Higher values results in more accurate guiding at the cost of speed. A value of 0 will continue the training until the last sample.

### Surface

Use guiding at surfaces.

### Volume

Use guiding inside volumes.

## Lights subpanel

### Light Tree

When ticked use existing light tree. This will sample multiple lights more efficiently.

### Light Threshold

When Light Tree is unticked Light Threshold becomes available. Terminate light samples below this value. This speeds up the rendering at the cost of noise. A value of zero will disable the test. Then all light value will be calculated.

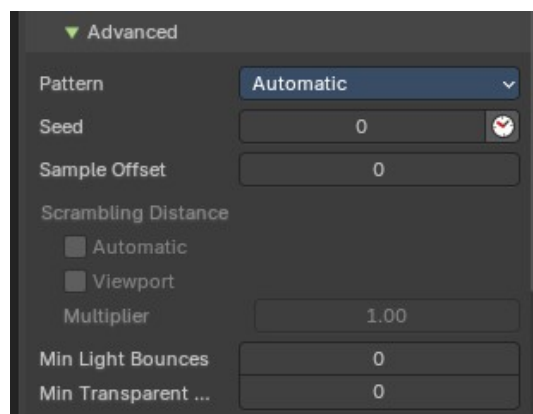

## Advanced subpanel

### Pattern

Random sampling pattern used by the integrator. You need to turn off Noise Threshold in the Render panel to activate and use the Sampling Pattern.

#### *Automatic*

Uses a progressive Multi-Jitter pattern to decide the random sampling pattern used by the integrator. This is a type of noise that allows the renderer to automatically decide the number of samples for each pixel, based on a target amount of noise. This can be very helpful in reducing render times while still maintaining a good level of detail.

## Classic

Uses a Sobol pattern to decide the random sampling pattern used by the integrator. This is a type of pattern that uses a mathematical sequence (the Sobol sequence) to decide the random sampling pattern. It's designed to cover the most space and ensure that all areas are adequately sampled

## Blue Noise

This is a type of noise that is high-frequency. In the context of rendering, it means the noise (or grain) you see in the image appears more like tiny dots scattered around, rather than clumps. This can make the image appear smoother and more pleasing to the eye.

## Seed

Seed value for integrator to get different noise patterns.

## Animate Seed

The clock icon besides the Seed value. Enable it to get different seed values for animation. Without animated seed you will get visible patterns in animations.

## Sample Offset

Number of samples to skip when starting the render.

## Scrambling Distance

Speeds up the rendering times at the gpu at cost of possible artifacts. You need to turn off Adaptive Sampling in the Render or Viewport panel to activate and use the Scrambling Distance.

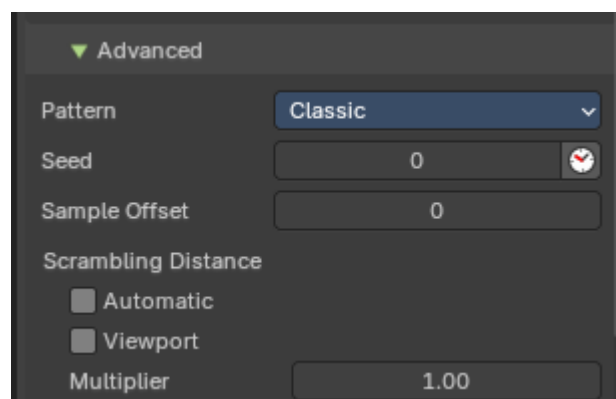

**Note:** *This is only available with Classic Sampling.*

## Adaptive

Instead of a fixed scrambling distance you can use this adaptive method. It is based on the sample count.

## Viewport

Also use the scrambling distance in the viewport.

## Multiplier

Speeds up the rendering at the GPU by scrambling pixels that are farer away. Lower values renders faster, with less noise – but too low values can lead to artifacts.

## Min Light Bounces

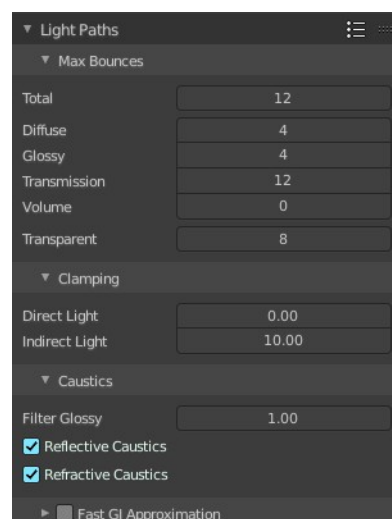

The minimum bounces of light rays.

## Min Transparent Bounces

The minimum number of transparent bounces.

## Light Paths panel

Here you will find all settings regarding light paths.

## Presets

In the header you will find a Presets menu to choose between presets and define your own presets.

## Max Bounces

A sub menu with the Maximum Bounces settings.

## Total

Total maximum number of bounces.

## Diffuse

Maximum number of diffuse bounces.

## Glossy

Maximum number of glossy bounces.

## Transmission Bounces

Maximum number of transmission bounces.

## Volume

Maximum number of volume scattering bounces.

## Transparent

Maximum number of transparency bounces.

---

## Clamping

A sub menu with the Clamping settings. Clamping will reduce noise at the cost of accuracy.

## Direct Light

The maximum value for a direct sample. Zero means disabled.

## Indirect Light

The maximum value for an indirect sample. Zero means disabled.

---

## Caustics

A sub menu with caustics and filter glossy settings.

## Filter Glossy

When using a value higher than 0.0, this will blur glossy reflections after blurry bounces, to reduce noise at the cost of accuracy. 1.0 is a good starting value to tweak.

Some light paths have a low probability of being found while contributing much light to the pixel. As a result these light paths will be found in some pixels and not in others, causing fireflies. An example of such a difficult path might be a small light that is causing a small specular highlight on a sharp glossy material, which we are seeing through a rough glossy material. In fact in such a case we practically have a caustic.

With path tracing it is difficult to find the specular highlight, but if we increase the roughness on the material, the highlight gets bigger and softer, and so easier to find. Often this blurring will hardly be noticeable, because we are seeing it through a blurry material anyway, but there are also cases where this will lead to a loss of detail

in lighting.

## Reflective Caustics

Disable reflective caustics. Path tracing supports rendering of caustics with a sufficient number of samples. But in practice it may be inefficient to the point that there is just too much noise.

## Refractive Caustics

Disable refractive caustics. Path tracing supports rendering of caustics with a sufficient number of samples. But in practice it may be inefficient to the point that there is just too much noise.

## Fast GI approximation subpanel

Approximate diffuse indirect light with background tinted ambient occlusion.

This method provides a fast alternative to full global illumination, for interactive viewport rendering or final renderers with lower quality.

## Fast GI Approximation checkbox

The checkbox in the header activates the Fast GI Approximation.

## Method

The fast gi method.

## Replace

Replace global illumination with ambient occlusion after a specified number of bounces.

## AO Factor

Factor of ambient occlusion blending.

## AO Distance

The length of the rays that are used for Ambient Occlusion. Defines how far any other faces gives the occlusion effect.

## Viewport Bounces

Use approximate global illumination after this number of light bounces in the viewport. A value of 0 deactivates the feature.

## Render Bounces

Use approximate global illumination after this number of light bounces in the rendering. A value of 0 deactivates the feature.

## Add

Add ambient occlusion to diffuse surfaces

## AO Factor

Factor of ambient occlusion blending.

## AO Distance

The length of the rays that are used for Ambient Occlusion. Defines how far any other faces gives the occlusion effect.

# Volumes panel

Adjust the volume sampling.

## Step Rate Render

Globally adjust detail for volume rendering for the final rendering. Lower values give more accurate and detailed results but also increased render time.

## Step Rate Viewport

Globally adjust detail for volume rendering for the viewport rendering. Lower values give more accurate and detailed results but also increased render time.

## Max Steps

Maximum number of steps through the volume before giving up, to protect from extremely long render times with big objects or small step sizes.

# Curves panel

Adjust the settings for Hair particles.

## Shape

Choose between the shape 3D Curves and Rounded Ribbon.

## Curve Subdivisions

Rounded Ribbons, the number of subdivisions at the curves.

## Viewport Display subpanel

How to display the hairs in the viewport.

### Shape

The hair shape type. Stand or Strip.

### Additional Subdiv

Additional subdivision along the hair.

## Simplify panel

Sometimes you want to simplify the rendering without to loose the already tweaked settings and adjustments. For test renderings for example. Simplify allows you to set global limits on subdivision, shadow samples and more.

### Enable

In the header is a checkbox to enable Simplify.

### Viewport

This section affects the rendering with cycles in the Viewport.

#### Max Subdivisions

Limit the number of maximum subdivisions.

#### Child Particles

Limit the number of child particles.

#### Texture Limit

Automatically scales down textures to the chosen value.

#### AO Bounces

Limit the number of Ambient Occlusion Bounces.

#### Volume Resolution

Simplify volumes by adjusting volume percentage of volume objects in viewport.

## Render

This section affects the final rendering.

### Max Subdivisions

Limit the number of maximum subdivisions.

### Child Particles

Limit the number of child particles

### Texture Limit

Automatically scales down textures to the chosen value.

---

## Culling

Contains Culling settings. Culling means that the affected geometry is excluded from calculation.

### Use Camera Cull

Allow objects to be culled based on the Camera Frustum. Frustum is the region of the 3D space that gets displayed by the camera, the field of view.

#### *Camera cull margin*

The margin for the camera space culling.

---

### Use Distance Cull

Allow objects to be culled based on the distance to the camera.

#### *Distance*

The distance after which the objects gets culled away.

---

## Grease Pencil

### Playback Only

Simplify the grease pencil strokes only during playback.

### Fill

Display Fill strokes in viewport.

## Modifiers

Display Modifiers.

## Shader Effects

Display Shader effects.

## Layers Tinting

Display layer tint.

## Antialiasing

Use antialiasing to smooth stroke edges.

## Motion Blur panel

Enable Motion Blur and adjust the settings.

Each object has also its own settings to control motion blur. These options can be found in the corresponding Object tab of the Properties editor.

### Enable

In the header is a checkbox to enable Simplify.

### Position

Controls at what point the shutter opens in relation to the frame.

### Shutter

Time between frames over which motion blur is computed. Shutter time 1.0 blurs over the length of 1 frame, 2.0 over the length of two frames, from the previous to the next.

### Rolling Shutter

Enable Rolling Shutter.

### Duration

With method Top - Bottom only. Controls balance between pure rolling shutter effect and pure motion blur effect. With zero being no rolling shutter and one being all rolling shutter.

## Shutter Curve

Shutter curve is a sub menu wAdjust a curve for the shutter effect.

### Navigation elements

The navigation elements at the top are described from left to right.

### Zoom in and out

The two buttons with the magnifying glass at it zooms in and out in the curve window.

### Tools

Tools is a menu that contains some curve related tools.

### Reset View

Resets the curve windows zoom.

### Vector Handle

Set handle type to Vector.

### Auto Handle

Set handle type to Auto.

### Auto Clamped Handle

Set handle type to Auto Clamped.

### Extend Horizontal

Causes the curve to stay horizontal before the first point and after the last point.

### Extend Extrapolated

Causes the curve to extrapolate before the first point and after the last point, based on the shape of the curve.

### Reset Curve

Resets the curve to the initial shape.

---

## Use Clipping

Clipping options. Set up clipping for the stroke.

## Delete Points

Deletes selected curve points.

---

## X and Y values

The coordinates of the currently selected curve point.

## Presets

At the bottom you can find some curve presets.

## Film panel

### Exposure

Exposure can be used to change the brightness of an image. Different then the Exposure option found in the Color management panel this exposure option works is on the data while the Color management exposure is on the view.

### Pixel Filter

The Pixel Filter randomly changes the coordinates of every sample with the given distribution. For example: When the Sobol Sampling Pattern samples near the edge of the pixel, the neighboring pixel might be lit instead with a rather high probability. Pixel filter is used to get rid of aliasing on the sharp edge of very bright objects, like mesh lights.

### Type

Choose the pixel filter type.

### Width

Adjust the pixel filter width.

## Performance panel

Settings to influence the render performance.

### Presets

Performance presets can be applied to quickly configure Cycles.

#### **Default**

This preset are the default cycles settings.

#### **Faster Rendering**

This preset is dedicated to speed with higher memory usage. This may be more unstable due to hardware limits.

#### **Lower Memory**

This preset is dedicated to lower memory. This may cause longer renders.

## Threads

With threads, you are able to to assign as many cores as you need from your CPU as dedicated resources. Default is Auto-Detect.

### Mode

#### **Auto-detect**

Automatically chooses the amount threads to match the number of logical processors on your computer.

#### **Fixed**

Manually choose the amount threads to use for rendering.

### Threads

Just active when you choose Fixed. Number of threads that you want to use.

## Memory

### Auto Tiles

Automatically render high resolution images in tiles to reduce memory usage. Tiles are cached to disk while rendering, to save memory.

### Tile Size

The tile size for the tiles.

## Acceleration Structure

### Use Spatial Splits

Spatial splits improve rendering performance in scenes with a mix of large and small polygons. The downsides are longer BVH build times and slightly increased memory usage.

### With CPU rendering:

#### **Use compact BVH**

Use a compact BVH code structure that uses less ram. This option renders slower.

### With GPU rendering:

#### **BVH Time Steps**

Is just active when Spatial Splits is off. Split BVH Primitives by this number of time steps. This speeds up rendering, but requires more memory.

## Use Hair BVH

Use a special type of BVH for rendering hair. The bounding boxes are not axis aligned allowing a spatially closer fit to the hair geometry. Disabling this option will reduce memory, at the cost of increasing hair render time.

## Final Render

### Persistent Data

Keep image data in memory after rendering, for faster re-renders at the cost of extra memory usage when performing other tasks in Blender.

## Viewport

This settings is for rendering in the Viewport.

### Pixel Size

Pixel Size for Viewport Rendering.

## Bake panel

Texture baking is the process to bake specific informations from one object into the texture or the vertex colors of another object. Ambient Occlusion. Or a Normal Map for example.

### NOTE

**Baking into textures requires to have a working UV mapping and a texture at the target object!**

How to use: Select the source object where you want to bake from, hold down Shift, select the target object where you want to bake to, so that both objects are selected. Adjust the settings to your needs. Then hit the Bake button.

### NOTE

The Bake panel is visible in all Modes. But you have to bake in Object Mode.

## Settings for all Texture types

Most settings in the Bake panel are available for all texture types.

## Bake Button

Start the bake process.

## Bake from Multires

Bake directly from multi resolution object.

---

## Bake Type

Bake Mode is a drop-down box to choose what type of information you want to bake from the source object into the texture or the vertex colors of the target object.

You can bake Subsurface, Transmission, Glossy, Diffuse, Environment, Emit, UV, Normal, Shadow, Ambient Occlusion and Combined.

### ***Combined***

Bakes the full rendering, means materials, textures, lightning, into the texture of the target object. Except Specularity.

### ***Ambient Occlusion***

Bakes ambient occlusion as specified in the World panels. Ignores all lights in the scene.

### ***Shadow***

Bakes the Shadow into the texture of the target object.

### ***Position***

Bake out a position map. Position maps stores the distance from the floor. Which allows to add a dirtmap above some ground for example.

### ***Normal***

Creates a Normal map by using the normals of the source object, and baking them as colors into the texture of the target object.

### ***UV***

Bakes colors of materials and textures only, without shading.

### ***Roughness***

Bakes the Roughness of a material into the texture of the target object.

### ***Emit***

Bakes the Emission or the glow color of a material into the texture of the target object.

### ***Environment***

Bakes the Environment texture into the texture of the target object. As seen from the center of the object.

## **Diffuse**

Bake the diffuse texture of the source object into the texture of the target object.

## **Glossy**

Bakes the Glossy Passes of a material into the texture of the target object.

## **Transmission**

Bakes the transmission Passes of a material into the texture of the target object.

---

## **Influence Sub panel**

Adjust what data contributes to the bake process. The items are self explaining.

The content changes, dependent of what type you want to bake.

## **Glossy, Diffuse**

### **Direct**

Add direct Light.

### **Indirect**

Add indirect Light.

### **Color**

Add Color.

---

## **Normal**

### **Space**

A drop-down box to chooses the Normal Space to use.

### **Swizzle**

Axis to bake in red, green and blue channels.

---

## **Combined**

### **Direct**

Bake directly from Multires mesh.

### **Indirect**

Normalizes without using material settings.

## Diffuse

Bake with Diffuse.

## Glossy

Bake with Glossy.

## Transmission

Bake with Transmission.

## Subsurface

Bake with Subsurface.

## AO

Bake with Ambient Occlusion.

## Emit

Bake with Emit.

---

## Selected to Active

The usual way to bake is first select the Source Object, where you want to bake from, hold down Shift, select the target object where you want to bake to, so that both objects are selected. Then hit the Bake button. That's Selected to Active.

## Extrusion

Inflate the active object by the specified distance for baking.

## Cage

Cast Rays to active object from a cage. A value of zero means unlimited ray length.

## Cage Object

Pick an object to use as a cage. Usually you create this cage object by duplicating the original object, and extrude out the faces along their normals until they fully include the original object.

## Ray Distance

Distance to use for the inward ray cast when using Selected to Active.

---

## Output Sub panel

## **Target**

To what target to bake. You can bake to images or you can bake to the vertex colors of the mesh. Note that baking to vertex colors has no further options.

## **Clear Image**

Clear clears the target image before baking.

## **Margin sub subpanel**

Adjust the margin width.

## **Type**

The margin type.

## **Adjacent Faces**

Use pixels from adjacent faces across UV seams to create the margin.

## **Extend**

Use the pixels at the inside of the border UV seams, and extend from there to create the margin.

## **Size**

The size of the margin around the UV patches.

## Render Tab

There are three different render engines available. Workbench, EEVEE, and Cycles. This chapter has a focus on the EEVEE render engine.

## Sampling panel

### Viewport subtab

#### Samples

The number of samples when rendering in the viewport.

#### Temporal Projection

Denoise image using a method called temporal reprojection. This method can leave some ghosting.

### Render subtab

#### Samples

The number of samples when rendering to file.

### Shadows subtab

#### Rays

The number of samples when rendering to file.

#### Steps

Amount of shadow ray sample per shadow ray.

#### Volume Shadows

Generate shadows from volumetric material. This is very resources hungry.

#### Steps

Number of samples to compute volumetric shadowing.

#### Resolution

The resolution scale of the shadow map.

## Clamping panel

In this panel you can clamp the light values to minimum and maximum values.

### Surface subtab

#### Direct Light

The maximum value for lights contribution on a surface. A value of zero disables this feature. Higher values will be scaled down to avoid too much noise and slow convergence at the cost of accuracy. Used by light objects.

#### Indirect Light

The maximum value for indirect lighting on a surface. A value of zero disables this feature. Higher values will be scaled down to avoid too much noise and slow convergence at the cost of accuracy. Used by ray-tracing and light-probes.

### Volume subtab

#### Direct Light

The maximum value for lights contribution in volumes. A value of zero disables this feature. Higher values will be scaled down to avoid too much noise and slow convergence at the cost of accuracy. Used by light objects.

#### Indirect Light

The maximum value for indirect lighting in volumes. A value of zero disables this feature. Higher values will be scaled down to avoid too much noise and slow convergence at the cost of accuracy. Used by light-probes.

## Raytracing panel

### Use Ray-Tracing

Use ray-tracing.

### Presets

Allows you to store raytracing presets. To add a new preset type in a new preset name into the edit box at the end of the list, and click at the + sign.

To remove a preset click at the - sign behind the name.

## Method

Select the tracing method to find scene-ray intersections.

### **None**

Do nothing.

### **Screen-Trace**

Raytracing against the depth buffer.

## Resolution

The ray-tracing resolution. 1 Ray per pixel, 1 ray per 4 pixel, 1 ray per 16 pixel.

## Clamp

Clamp ray intensity to reduce noise. Coose 0 to disable clamping.

## Screen tracing subpanel

Just visible with the method Screen-Trace

### **Precision**

Precision of screen space ray-tracing.

### **Thickness**

Surface Thickness used to detect intersection when using screen-tracing.

## Denoising Subpanel

### **Denoising**

Enable Denoising for raytraced effects.

### **Spatial Reuse**

Reuse the rays of neighbour pixe.

### **Temporal Accumulation**

Accumulate samples by reprojecting last tracing results

### **Bilateral Filter**

Blur the resolved radiance by reprojecting last tracing result of the temporal accumulation.

## Fast GI Approximation subpanel

### Method

#### Global Illumination

Computes global illumination. It takes light bounces off surrounding objects into account.

#### Ambient occlusion

Uses Ambient occlusion instead of Global Illumination. Ambient Occlusion is self shadowing, and doesn't calculate colors.

### Resolution

The resolution of the AO or GI map. It is relative to the render resolution. 1 is the size of the full render resolution, 1/2 is half the size of render resolution, and so on.

### Rays

Amount of GI or AO rays to trace for each pixel.

### Steps

Amount of screen sample per GI or AO ray.

### Precision

Precision of the Fast GI ray matching.

### Distance

If non zero, the maximum distance at which other surfaces will contribute to the Fast GI approximation.

### Thickness near / far

Geometric thickness of the surfaces when computing GI or AO. This feature reduces light leaking and missing contact occlusion.

### Bias

Bias the shading normal to reduce self intersection artifacts.

## Volumes panel

Contains volumetrics settings.

### Resolution

The resolution of the Volumes map. It is relative to the render resolution. 1 is the size of the full render resolution, 1/2 is half the size of render resolution, and so on.

### Steps

Number of samples to compute for the volumetrics effect.

### Distribution

Distribute more samples closer to the camera.

### Max Depth

Maximum surface intersection count used by the accurate volume intersection method. This feature will create artifacts if it is exceeded.

### Custom Range subpanel

Enable custom start and end distances for volume computation.

### Start / End

The start and end values for computation.

## Curves panel

### Shape

Choose if the hair is displayed as strand or as strip.

### Additional Subdiv

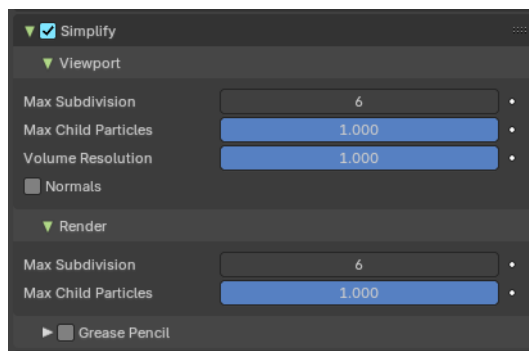

Additional subdivision along the hair.

## Simplify panel

Sometimes you want to simplify the rendering without to loose the already tweaked settings and adjustments. For test renderings for example. Simplify allows you to simplify the rendering.

### Enable

In the header is a checkbox to enable Simplify.

### Viewport subpanel

This section affects the rendering with Eevee in the Viewport.

#### Max Subdivisions

Limit the number of maximum subdivisions.

#### Max Child Particles

Limit the number of child particles.

#### Volume Resolution

Simplify volumes by setting the resolution percentage of volume objects in viewport.

#### Normals

Skip computing custom normals and face corner normals for displaying meshes in the viewport.

### Render

This section affects the rendering with Eevee to file.

#### Max Subdivisions

Limit the number of maximum subdivisions.

#### Max Child Particles

Limit the number of child particles.

### Grease Pencil

This section affects Grease Pencil drawings.

## Enable

Enables the Grease Pencil features.

## Playback Only

Simplify Grease Pencil only during animation playback.

## Fill

Display Fill strokes in the Viewport.

## Modifiers

Apply modifiers in the viewport.

## Shader Effects

display shader effects.

## Layers Tinting

Display layers tint.

## Antialiasing

Use antialiasing to smooth stroke edges.

## Depth of Field panel

### Max Size

The maximum size of the bokeh shape for Depth of Field. Lower is faster.

### Sprite Threshold

Brightness threshold for using sprite base depth of field.

### Neighbor Rejection

The maximum brightness to consider when rejecting bokeh sprites based on neighborhood. Lower is faster.

### Jitter Camera

Jitter the camera to create accurate blurring by using render samples.

### Overblur

Apply blur to each jittered sample to reduce undersampling artifacts.

## Motion Blur panel

Enable Motion Blur and adjust the settings.

Each object has also its own settings to control motion blur. These options can be found in the corresponding Object tab of the Properties editor.

### Enable

In the header is a checkbox to enable Simplify.

### Position

Controls at what point the shutter opens in relation to the frame.

### Shutter

Time taken in frames between shutter open and close.

### Bleeding Bias

Reduce background bleeding onto foreground elements. Lower values = less bleeding.

### Max Blur

The maximum blur distance that a pixel can spread over.

### Steps

Controls the accuracy of motion blur. More steps means longer render time.

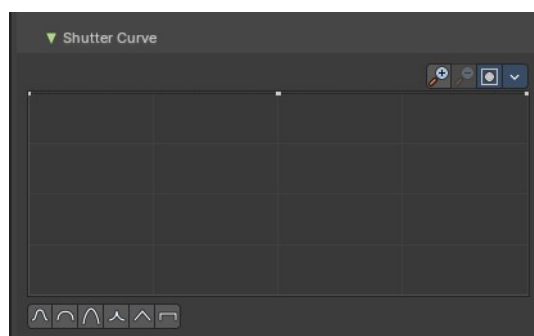

### Shutter Curve

Sutter curve is a sub menu wAdjust a curve for the shutter effect.

### Navigation elements

The navigation elements at the top are described from left to right.

### Zoom in and out

The two buttons with the magnifying glass at it zooms in and out in the curve window.

## Use Clipping

Clipping options. Set up clipping for the stroke.

## Tools

Tools is a menu that contains some curve related tools.

### Reset View

Resets the curve windows zoom.

### Extend Horizontal

Causes the curve to stay horizontal before the first point and after the last point.

### Extend Extrapolated

Causes the curve to extrapolate before the first point and after the last point, based on the shape of the curve.

### Reset Curve

Resets the curve to the initial shape.

---

## Handles

### Vector Handle

Set handle type to Vector.

### Auto Handle

Set handle type to Auto.

### Auto Clamped Handle

Set handle type to Auto Clamped.

## X and Y values

The coordinates of the currently selected curve point.

## Presets

Curve presets.

## Delete Points

Deletes selected curve points.

## Film panel

### Filter Size

The width over which the reconstruction filter combines samples.

### Animate Property

This property can be animated. Activating this button sets a keyframe.

### Overscan

Internally render past the image borders to avoid screen space effects disappearing.

### Overscan Size

How much bigger the image should be internally rendered.

## Performance panel

### High Quality Normals

Use high quality tangent space. Slower but more accurate.

### Memory Subpanel

### Shadow Pool

How much shadow data can be allocated for the scene. More ram usage means more possible shadows. This affects the GPU ram usage.

### Light Probes Volume Pool

How much Light probes Volume data can be allocated for the scene. More ram usage means more possible light probes volumes. This affects the GPU ram usage.

## Viewport Subpanel

### Pixel Size

The pixel size for viewport rendering.

Automatic depends of the user interface scale. 1 renders at full resolution. 8 renders just in 12.5% of the size.

## Compositor Subpanel

Realtime compositor settings.

### Device

Which device to use for realtime compositing.

### Precision

#### **Auto**

Full precision at rendering, half precision otherwise.

#### **Full**

Full precision in all cases.

## Render Tab

There are three different render engines available. Workbench, Eevee, and Cycles. This chapter has a focus on the Eevee render engine.

## Workbench - Performance panel

### High Quality Normals

Use high quality tangent space. Slower but more accurate.

## Sampling panel

### Viewport Samples

The number of samples when rendering in the viewport.

### Render

The number of antialias samples when rendering to file.

### Viewport

The number of antialias samples when rendering in viewport.

## Lighting panel

The Workbench renderer uses Open GL. OpenGL rendering is not influenced by the lights that you place in the workspace. But by a special OpenGL light setup. It can be tweaked in the Lighting panel and the User Preferences.

## Flat

Use a flat lighting.

## Studio

Use a Studio light setup.

## Light library browser

Choose a predefined studio light setup.

## Rotation

Rotate the studio light setup.

## User Preferences

A click at this button opens up the user preferences where you can add and manage the OpenGL Lights.

## Matcap

Use Matcaps to render the scene.

## User Preferences

A click at this button opens up the user preferences where you can add and manage the Matcaps.

## Flip Matcap

Flips the matcap.

# Color panel

Workbench renderer is meant for fast preview display. It does not use materials like Eevee or Cycles. You choose a color instead.

This panel allows you to define the color of the surface of the object. This

settings are also dependent of the chosen lighting.

## Material

Uses the material including textures for the mesh.

## Object

Uses the Object color.

## Vertex

Uses the Vertex color.

## Single

Uses a single color for the selected mesh.

## Random

Uses a random color for the mesh.

## Texture

Renders the texture, and ignores the material settings.

## Options panel

### X Ray

Render the faces transparent.

### Backface Culling

Don't calculate back faces.

### Show X-Ray

Set X-Ray active, and adjust the amount of alpha that is used for the x-ray effect.

Note that you can have either X-Ray or Shadow and Cavity active. Not both at the same time.

### X-Ray Alpha

This slider shows up when you tick Show X Ray. Adjust the intensity.

## Shadow

Render Shadow.

## Shadow Intensity

This slider shows up when you tick Shadow. Adjust the intensity.

## Shading Shadow Options

Adjust a shadow shift relative to the light source.

## Cavity

Show Cavity. Cavity highlights ridges and valleys in the scene geometry. Once activated Cavity shows some further settings.

## World

Draw the cavity shading in world space.

## World Space / Ridge Valley

Factor for the cavity ridges and valleys.

## Shading Options

Adjust samples, distance and attenuation for the cavity ridges and valleys.

## Screen

Draw the cavity shading in Screen space.

## Screen Space / Ridge Valley

Factor for the curvature ridges and valleys.

## Both

Draw the cavity shading in both, World Space and Screen space.

Settings see above.

## Outline

Show the not selected objects with an outline.

## Outline Color

Define the color of the outline for not selected objects.

## Specular Lighting

Render specular highlights.

### Simplify panel

Sometimes you want to simplify the rendering without to loose the already tweaked settings and adjustments. For test renderings for example. Simplify allows you to set global limits on subdivision, shadow samples and more.

### Enable

In the header is a checkbox to enable Simplify.

### Viewport

This section affects the rendering with cycles in the Viewport.

### Max Subdivisions

Limit the number of maximum subdivisions.

### Max Child Particles

Limit the number of child particles

### Volume Resolution

Simplify volumes by adjusting volume percentage of volume objects in viewport.

### Render

This section affects the final rendering.

### Max Subdivisions

Limit the number of maximum subdivisions.

### Max Child Particles

Limit the number of child particles.

## Grease Pencil

### Playback Only

Simplify the grease pencil strokes only during playback.

### Fill

Display Fill strokes in viewport.

### Modifiers

Display Modifiers.

### Shader Effects

Display Shader effects.

### Layers Tinting

Display layer tint.

### Antialiasing

Use antialiasing to smooth stroke edges.

## Render Tab

Rendering is the process of calculating a 2D image (or video) from your 3D scene. For this you use a so called render engine.

The Render tab contains the functionality and settings around the available render engines in Bforartists. and here you can choose the renderer with which you render your still or animation.

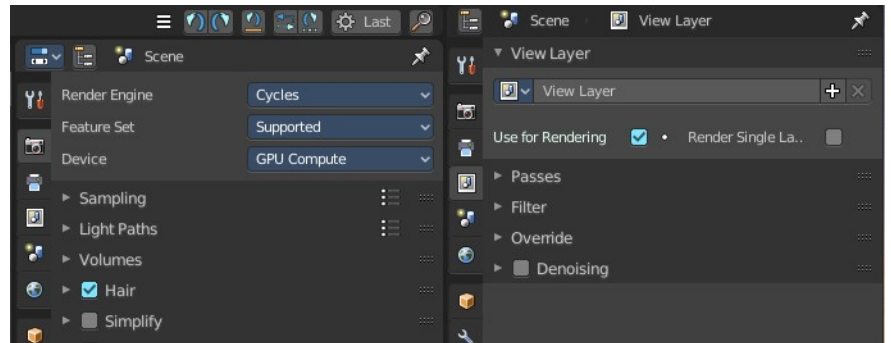

There are three different render engines available: Workbench, Eevee, and Cycles.

Cycles is a so called offline renderer. It is an unbiased physically correct renderer with some biased adjustments to make it usable for animations.

Cycles can render at the CPU or the GPU.

Eevee and Workbench are so called Realtime Renderers. They render on the GPU. Workbench relies at the OpenGL render features of the graphics card. Eevee is a full independent realtime render engine.

All renderers have different settings. And the choice of the renderer influences the tab and panel content of the whole Scene section.

This content will be covered in the chapters for the other tabs.

### Cycles Feature Set

When you choose Cycles then you will see a new drop down box called Feature set. Cycles has two feature set settings. Supported and Experimental.

Supported means you have all common Cycles settings available.

Experimental means that you have access to some further experimental features of Cycles, which are somehow functional, but are still experimental features. Like Adaptive subdivision. Those features may or may not work proper. Use at own risk!

## Cycles Device

When you turn on Cuda in the User Preferences then you will get a Device drop down box to choose if you want to render with the CPU or the GPU.

## Open Shading Language

When you render with Cycles at the CPU, then you can choose to use the Open Shading Language.

## EEVEE Feature Set

When you choose EEVEE, you will be able to use a raster based render engine that uses your GPU to render light and materials. This includes features like screenspace raytraced reflections and global illumination, light and reflection volumes, raytraced cast shadows, and more.

This renderer is akin to modern game engine rendering techniques.

## Workbench Feature Set

When you choose Workbench, this use the internal viewport rendering typical of mesh editing and playback. You can use matcaps and other viewport settings to render to disk from here.

**Note:** Changing these settings will also change the sequencer preview of scene strips.

## Grease Pencil panel

### Anti Aliasing Threshold

Threshold for edge detection algorithm.

Note that a higher value might overblur some image parts.

## Freestyle panel

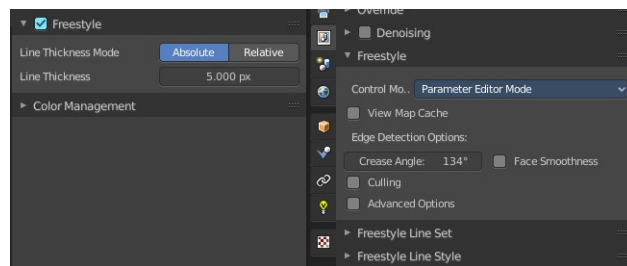

### What is FreeStyle?

Freestyle is an edge- and line-based non-photorealistic (NPR) rendering engine that works on top of the other engines except Eevee. It relies on mesh data and z-depth information to draw lines on selected edge types. Various line styles can be added to produce artistic or technical looks.

The two operating modes - *Python Scripting* and *Parameter Editor* - allow a diversity of line styles and results. Line styles such as Japanese big brush, cartoon, blueprint, thickness-with-depth are already pre-scripted in Python. The Parameter Editor mode allows intuitive editing of features such as dotted lines and easy setup of multiple line types and edge definitions.

There are more Freestyle settings in the View Layer tab wAdjust and define various parameters.

## Enable

In the header is a checkbox where you can enable the Freestyle renderer.

Enabling the checkbox reveals the Freestyle Settings in the View Layer Properties.

## Line Thickness Mode

### Absolute

The line thickness is given by a user-specified number of pixels. The default value is **1.0**.

### Relative

The unit line thickness is scaled by the proportion of the present vertical image resolution to **480** pixels. For instance, the unit line thickness is **1.0** with the image height set to **480**, **1.5** with **720**, and **2.0** with **960**.

## Line Thickness

Line Thickness is only available for *Absolute* line thickness. The base line thickness in pixels.

## Color Management panel

Color management is important to create renders and assets that are physically accurate and look great on multiple display devices. It is used both to ensure all parts of the pipeline interpret colors correctly, and to make artistic changes like exposure and color grading.

Bforartists color management is based on the OpenColorIO library. By using the same OpenColorIO configuration in multiple applications, the same color spaces and transforms will be available for consistent results.

In the Color Management panel you will find the settings around color management. It allows an artist to make sure that an image stays the same from rendering, to saving, to post-processing. Color management also allows an artist to tweak things like exposure, gamma, or the overall color grade.

The Color Management panel is the same for all render engines.

### Display Device

The device that the image is being viewed on. Your monitor.

Most computer monitors are configured for the sRGB color space.

### View Transform

Choose between different ways to view the image on the same monitor.

#### Standard

Does no extra conversion besides the conversion for the display device.

#### Khronos PBR Neutral

A tone mapper designed specifically for PBR color accuracy. It aims to get sRGB colors in the output render that match as faithfully as possible the input sRGB baseColor under gray-scale lighting.

#### AgX

AgX is a further development to Filmic. It brings an implementation of False Colors view transform, and replaces Filmic-based. It is available for all display devices.

#### Filmic

For more photo realistic results and better handling of high dynamic range. The contrast can be adjusted by changing the *Look* option for the Filmic view transform.

## Filmic Log

Converts to Filmic log color space. This can be used for export to color grading applications, or to inspect the image by flattening out very dark and light areas.

## Raw

Intended for inspecting the image but not for final export. Raw gives the image without any color space conversion.

## False Color

Shows a heat map of image intensities, to visualize the dynamic range.

## Look

Adjust the contrast.

## Exposure

Used to control the image brightness (in stops) applied before color space conversion. The calculation is:  $output\_value = render\_value \times 2^{(exposure)}$

## Gamma

Extra gamma correction applied after color space conversion. Note that the default sRGB or Rec709 color space conversions already include a gamma correction of approximately 2.2 (except the *Raw* and *Log* views), so this would be applied in addition to that.

## Sequencer Color Space

The color space that the sequencer operates in. By default, the sequencer operates in sRGB space, but it can also be set to work in Linear space like the Compositing nodes, or another color space. Different color spaces will give different results for color correction, cross fades, and other operations.

## Display subpanel

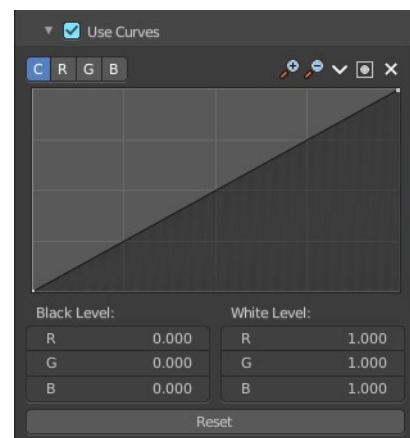

Enable High Dynamic range display in rendered viewport. This uncaps display brightness. And requires a monitor with HDR support and a view transform designed for HDR.

Filmic and AgX does not generate HDR colors. And so the option is greyed out.

## Use Curves subpanel

Adjust RGB Curves to control image colors before color space conversion.

## Navigation elements

The navigation elements at the top are described from left to right.

### Zoom in and out

The two buttons with the magnifying glass at it zooms in and out in the curve window.

## Tools

Tools is a menu that contains some curve related tools.

### Reset View

Resets the curve windows zoom.

### Vector Handle

Set handle type to Vector.

### Auto Handle

Set handle type to Auto.

### Auto Clamped Handle

Set handle type to Auto Clamped.

### Extend Horizontal

Causes the curve to stay horizontal before the first point and after the last point.

### Extend Extrapolated

Causes the curve to extrapolate before the first point and after the last point, based on the shape of the curve.

### Reset Curve

Resets the curve to the initial shape.

## Use Clipping

Clipping options. Set up clipping for the stroke.

## Delete Points

Deletes selected curve points.

## Black Level

The color that Black is mapped to.

## White Level

The color that White is mapped to.

## Hotkeys for Black and White Level

You may want to sample the black and white level colors directly in the image by clicking at an area. There are hotkeys for that.

**Ctrl + Left Mouse** click in the image sets the Black level value from that position.

**Shift + Left Mouse** click in the image sets the White Level value from that position.

To see the result you need to tick the View as Render button.

## **Reset**

Resets the Curve and the Black and White Level values to the default values.

## Output Properties Tab

The Output properties contains all the settings to render the final image or movie. Most of the settings are the same for all three available render engines.

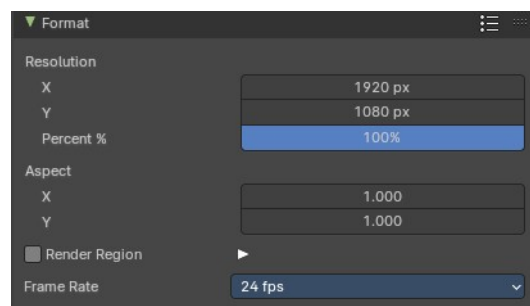

### Render Engine

Shows the active render engine. Specific renderers do have other settings. And you can also switch to another renderer. But note that this is more a visual guide. It misses the Cycles render settings.

## Dimensions Panel

This panel contains the dimension settings.

### Presets

A list of dimension presets with the most common settings.

To add a new preset type in a new preset name into the edit box at the end of the list, and click at the + sign.

To remove a preset click at the - sign behind the name.

### Resolution X / Y

The dimensions of the image in pixels.

%

Render the image in per cent of the original image. You can for example render in 200% of the resolution values. Or in 50%.

## Aspect X / Y

The image aspect ratio. For anamorphic or non square pixel output.

## Render Region

Activate render region for the output image.

There is a render region feature in the 3D view and in the Image editor where you can render a portion of the screen for preview purposes. Normally the output will always render the full image then, regardless of the render region. When you activate Render Region then the output will also render the render region only, and not the full image.

## Crop to Render Region

Crop the output image to the size of the render region.

## Frame Rate

The output frame rate. When you choose custom then two more properties appears.

## Frame Range Panel

### Frame Start / End

The start and end frame for an animation.

### Frame Step

Number of frames to skip forward while playing the animation. With a value of 2 every second frame gets skipped.

### FPS

The custom frame per seconds value.

### Base

Frame rate base. A multiplier that makes it for example possible to set up 29,97 Frames instead of 30 for NTSC.

## Time Stretching

Remap the length of an animation.

### Old

The old length.

### New

The new length.

## Stereoscopy Panel

Allows you to render out stereoscopic images from the active camera. For the anaglyph images you need special stereoscopy glasses to see the 3D effect. And in case of the interlace method a 3d ready monitor and shutter glasses.

The anaglyph method is to create stereo images. The interlace method is mostly used in movies.

## Workflow

Turn on Stereoscopy.

Select the Camera in the Outliner. In the Properties Editor choose the Object Data Properties tab (which should show a camera icon at this point), and open the Stereoscopy panel.

Change the Convergence Plane Distance to your needs. This can also be done in the 3D view with the handlers when you are in Camera view.

Interocular distance is the distance between the left and the right camera.

Outside of the camera view you will see this plane in front of the camera.

Adjust the plane to your needs. The plane is the reference point. Everything behind appears behind the focus. Everything before the plane appears before the focus.

In the sidebar in the 3D view you will find further settings.

Turn on volume to see if the objects are inside of the volume.

Do a preview rendering, and adjust the settings if required.

Go back to the Output tab to the Output panel. By activating stereoscopy here is a new section called Views. Here you can find further export settings.

## Stereo 3D / Multiview

The stereoscopy method. Stereo 3D uses two predefined virtual cameras. The camera settings gets inherited from the main camera.

Multiview allows you to set up several cameras manually. You need to create every camera by hand. And you need to follow name conventions to get this to work. In the outliner give the cameras the suffix that you want to use in the list. Here three cameras with a suffix.

Now do the same in the list of cameras. Give every camera the same suffix than in the outliner. The camera name is not important. Important is the suffix. This is the identifier.

And in the render window you have now the render result of your three cameras.

Note that for stereoscopy just two cameras gets used for rendering the anaglyph or interlaced result. Usually the ones with suffix \_L and \_R. So our third camera does not influence the stereoscopic image here.

## List of Cameras

The list of cameras. Note that with method Stereo 3D these cameras does not exist in the outliner. They are virtually created as child objects to the main camera that you use for rendering.

In this list you can choose the cameras to change the suffix.

The checkbox allows you to disable the cameras. Both options are just of interest for the multi-view setup. Normal stereoscopy setup does not require any further setup.

## Resize handler

The resize handler allows you to resize the list.

## Search field

The triangle button down left allows you to open a search field.

## Add / Remove / Rename

Add adds a custom camera. Remove removes a custom camera. And custom cameras can be renamed by clicking at the name.

The camera names left and right can't be renamed, and you can't remove them from the list. Individual cameras can be renamed and removed.

## Suffix

The camera identifier. The suffix gets appended at the end of the single images of the camera. The left camera has the suffix `_L`, and the right camera has the suffix `_R`

## Output Views Subpanel

This subpanel just shows with Stereoscopy enabled!

Adjust the stereoscopy export settings. Note that this settings does not adjust what you view in the image editor. This settings influences what you save from the image editor then.

## Individual

Save out single images from each camera when you save the result from the image editor. So for a stereoscopic image two images for the two cameras.

## Stereo 3D

Save out the stereoscopic image as a single image when you save the result from the image editor.

### Stereo Mode

How to export the stereoscopic image with save as in the image editor. There are four methods available.

### Stereo Mode Type Anaglyph

Render Views for left and right eyes as two differently filtered colors in a single image. You need anaglyph glasses to see the 3d effect.

### Anaglyph Type

The color model to display the graphics.

### Stereo Mode Type Interlace

Render Views from left and right eyes interlaced into a single image. You need a 3D Ready monitor to see the stereo effect.

### Interlace Type

The interlace type that you can choose.

### Swap Left/Right

Swaps left and right camera view.

## Stereo Mode Type Side by Side

Renders images of the two cameras side by side.

### ***Cross Eyed***

Swaps left and right camera view.

### ***Squeezed Frame***

Combine both views in a squeezed image.

## Stereo Mode Type Top Bottom

Renders images of the two cameras side by side.

### ***Squeezed Frame***

Combine both views in a squeezed image.

# Output Panel

The file output settings.

## File Path

The location to save rendered frames. Here you will find rendered animation sequences. For single images you can save out the result in the image editor.

When rendering an animation, the frame number is appended at the end of the file name with four padded zeros (e.g. `image0001.png`). You can set a custom padding size by adding the appropriate number of # anywhere in the file name (e.g. `image_##_test.png` translates to `image_01_test.png`).

This setting expands relative paths where a `//` prefix represents the directory of the current blend-file.

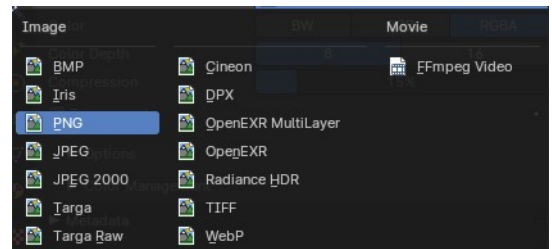

## Load File

Here you can load an existing file to overwrite it. Or you can use it to load a file in a directory and rename it then to your destination file name.

## File Format

The output file format.

Each file format has some own settings.

## Image file formats

### BMP

#### Color

The output color format. Black and white or rgb.

### Iris

#### Color

The output color format. Black and white, rgb or rgba.

### PNG

#### Color

The output color format. Black and white, rgb or rgba.

## Color Depth

8 or 16 colors per channel.

## Compression

The compression level.

## JPEG

### Color

The output color format. Black and white, or rgb.

### Quality

The jpeg quality.

## JPEG 2000

### Color

The output color format. Black and white, rgb or rgba.

### Color Depth

8, 12 or 16 colors per channel.

### Quality

The jpeg quality.

### Codec

Which jpeg 2000 codec to use.

### Cinema

Use OpenJpeg Cinema preset.

### Cinema (48)

Use OpenJpeg Cinema (48) preset.

### YCC

Save luminance / chrominance / chrominance channels instead of rgb channels.

## Targa

### Color

The output color format. Black and white, rgb or rgba.

## Targa Raw

### Color

The output color format. Black and white or rgb.

## Cineon

### Color

The output color format. Black and white, or rgb.

Gamma of 1.7 and Non-Linear is hard coded.

## DPX

### Color

The output color format. Black and white, rgb, or RGBA.

### Color Depth

8, 10, 12 or 16 colors per channel.

### Log

Convert to logarithmic color space.

## Open EXR Multilayer

### Color Depth

Float half values or Float full values per channel.

### Codec

What codec to use.

### Preview

When rendering animations, save Jpeg preview images into the same directory.

## Open EXR

### Color

The output color format. Black and white, rgb, or RGBA.

### Color Depth

Float half values or Float full values per channel.

### Codec

What codec to use.

### Preview

When rendering animations, save Jpeg preview images into the same directory.

## ***Radiance HDR***

### **Color**

The output color format. Black and white, or rgb.

## ***TIFF***

### **Color**

The output color format. Black and white, rgb, or RGBA.

### **Color Depth**

8 or 16 bit per channel.

### **Compression**

The compression method.

## ***WebP***

### **Color**

The output color format. Black and white, rgb, or RGBA.

## ***FFmpeg video***

### **Color**

The output color format. Black and white, or rgb.

## **Transparent**

Eevee, Eevee (Legacy), and Workbench renderer. Render and export the result with transparent background.

## **Options subpanel**

Not all options are available for all file formats.

### **Saving**

#### ***File Extensions***

Adds the correct file extensions per file type to the output files.

#### ***Cache Result***

Saves the rendered image and passes to a Multilayer EXR-file in temporary location on your hard drive. This

allows the compositor to read these to improve performance, especially for heavy compositing.

## Image Sequence

### **Override**

Override existing files when rendering.

### **Placeholders**

Create empty placeholder frames while rendering.

---

## Color management subpanel

### Color management settings

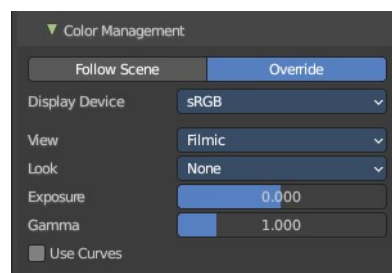

#### **Follow scene**

Uses the color management from the scene.

#### **Override**

Uses the color management settings that is defined below instead of the color management from the scene.

This settings is in most parts equal to the color management settings in the render properties. But has no settings for the Sequencer.

### Display Device

The device that the image is being viewed on. Your monitor.

Most computer monitors are configured for the sRGB color space.

Color management can also be disabled by setting the device to None.

---

### View Transform

Choose between different ways to view the image on the same monitor.

#### **Standard**

Does no extra conversion besides the conversion for the display device.

#### **Filmic**

For more photo realistic results and better handling of high dynamic range. The contrast can be adjusted by changing the *Look* option for the Filmic view transform.

## Filmic Log

Converts to Filmic log color space. This can be used for export to color grading applications, or to inspect the image by flattening out very dark and light areas.

## Raw

Intended for inspecting the image but not for final export. Raw gives the image without any color space conversion.

## False Color

Shows a heat map of image intensities, to visualize the dynamic range.

## Look

Adjust the contrast.

## Exposure

Used to control the image brightness (in stops) applied before color space conversion. The calculation is:  $output\_value = render\_value \times 2^{(exposure)}$

## Gamma

Extra gamma correction applied after color space conversion. Note that the default sRGB or Rec709 color space conversions already include a gamma correction of approximately 2.2 (except the *Raw* and *Log* views), so this would be applied in addition to that.

## Use Curves

Adjust RGB Curves to control image colors before color space conversion.

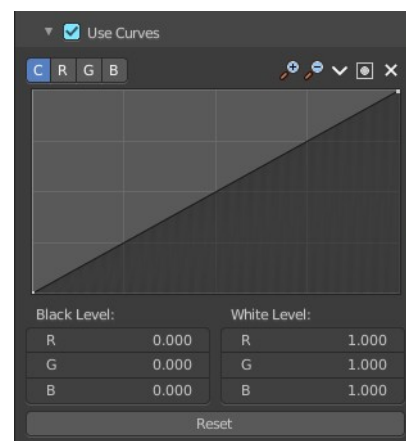

## Navigation elements

The navigation elements at the top are described from left to right.

## Zoom in and out

The two buttons with the magnifying glass at it zooms in and out in the curve window.

## Tools

Tools is a menu that contains some curve related tools.

## Reset View

Resets the curve windows zoom.

### **Vector Handle**

Set handle type to Vector.

### **Auto Handle**

Set handle type to Auto.

### **Auto Clamped Handle**

Set handle type to Auto Clamped.

### **Extend Horizontal**

Causes the curve to stay horizontal before the first point and after the last point.

### **Extend Extrapolated**

Causes the curve to extrapolate before the first point and after the last point, based on the shape of the curve.

### **Reset Curve**

Resets the curve to the initial shape.

---

### **Use Clipping**

Clipping options. Set up clipping for the stroke.

### **Delete Points**

Deletes selected curve points.

---

### **Black Level**

The color that Black is mapped to.

### **White Level**

The color that White is mapped to.

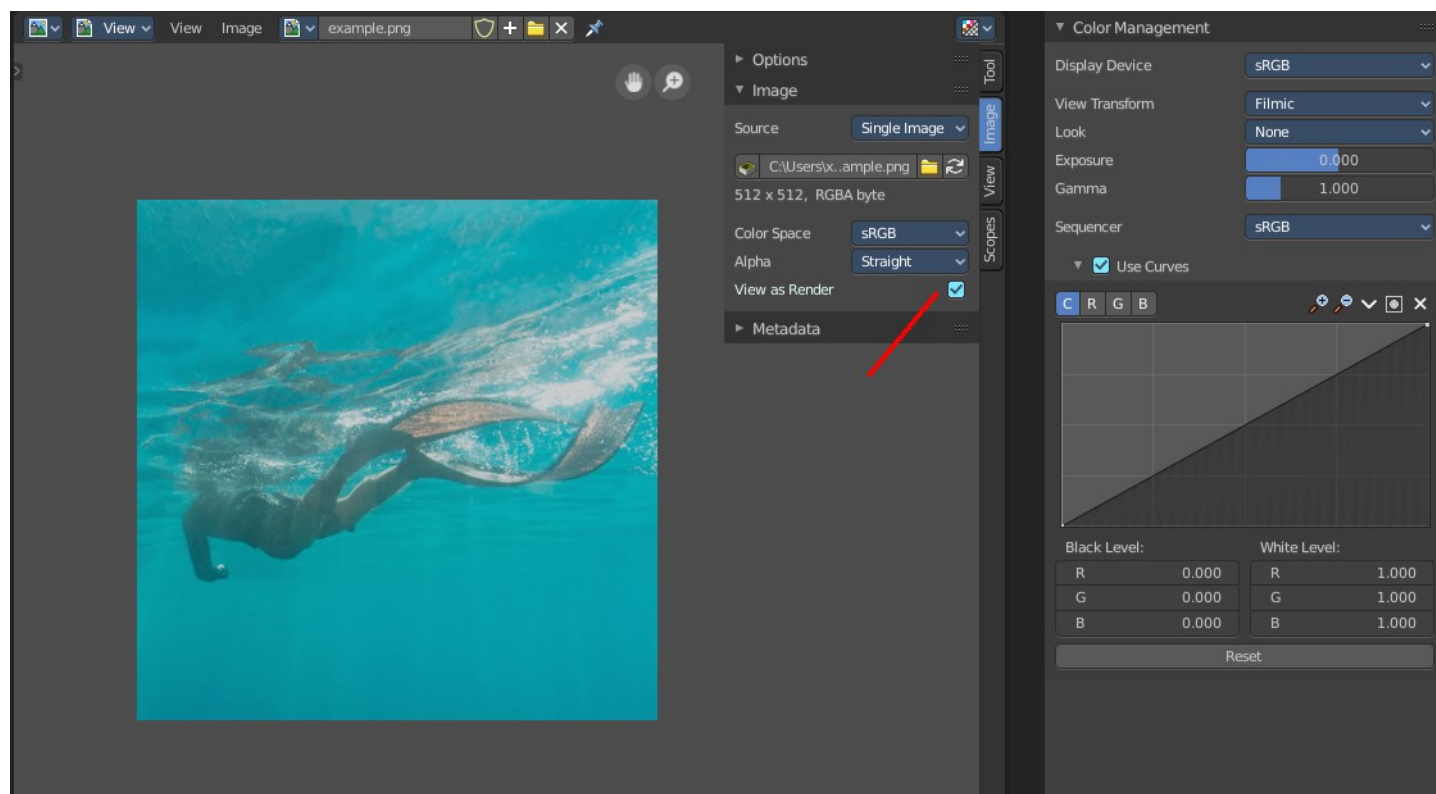

### **Hotkeys for Black and White Level**

You may want to sample the black and white level colors directly in the image by clicking at an area. There are hotkeys for that.

**Ctrl + Left Mouse** click in the image sets the Black level value from that position.

**Shift + Left Mouse** click in the image sets the White Level value from that position.

To see the result you need to tick the View as Render button.

### **Reset**

Resets the Curve and the Black and White Level values to the default values.

### **Transparent subpanel**

Cycles only. Enable the rendering of transparent background.

### **Transparent Glass**

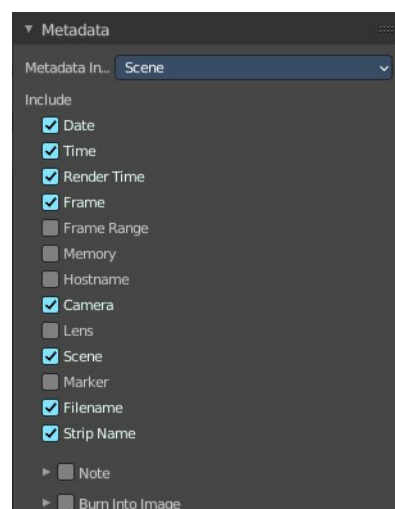

Render glass with transparent background.

### **Roughness Threshold**

For transparent transmission. Keep surfaces with roughness above the threshold opaque.

# Metadata Panel

What metadata to include into the image or movie.

## Metadata Input

Where to get the Metadata from.

## Include

What Metadata to include.

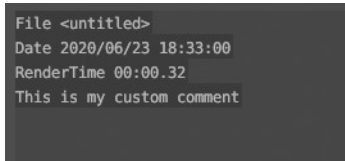

## Note

Include a custom comment.

## Burn into Image

Render the stamp info text into the image. The information is cluttered across the rendered image. Parts of it appears up left in the rendering. Parts down left, and parts down right.

The props have decorators. This means this information can be keyframed. The font itself is the system font, and cannot be changed.

## Font Size

The font size.

## Text Color

The text color.

## Background

The background color of the text.

## Include Labels

Display stamp labels like "Camera" in front of camera name, etc.

# Post Processing Panel

Enable Post Processing.

## Pipeline

### Compositing

Process the pipeline through the compositing in case compositing nodes are enabled.

### Sequencer

Process the pipeline (and composited result) through the video sequence pipeline in case Sequencer strips exists.

### Dither

Amount of dithering noise added to the rendered image to break up banding.

This prop has a decorator, and can be keyframe animated.

## View Layer

View Layers reference to Scene collections. They allow to set their visibility, selectability and other options. Each View Layer can use any collection you wish, and multiple View Layers can use the same collections or different collections.

Usually you have just one View layer for the whole scene. But you can create more View layers in the header, and rename them there.

View layers are by default active for all collections. You can exclude them for specific layers in the Outliner. Select the view layer, and turn off the collections that you don't want to have active in this view layer.

Note. The different render engines uses different view layer functionality. And so the panels and available options differs.

## Render Engine

Shows the active render engine. Specific renderer does have other settings. And you can also switch to another renderer. But note that this is more a visual guide. It misses the Cycles render settings.

## View Layer Panel - All Renderers

### View Layer Prop

### View Layer list

The list of available view layers

### View Layer edit box

Set the active view layer, and view and edit the name of the current active view layer. Click into the edit box to edit the name.

## Add View Layer

Adds a new view layer.

## New

Adds a new view layer with the default content.

## Copy Settings

Adds a new view layer with the content of the current active layer.

## Blank

Adds a new view layer and deactivates all collections.

## Remove View Layer

Removes the selected view layer.

## Use for Rendering

Disable or enable the render layer.

## Animate Property

This property can be animated. Activating this button sets a keyframe at the current frame.

## Render Single Layer

Only render the active layer. This just works for rendering from the interface. Rendering from command line ignores this setting.

## Passes panel - EEVEE

Here you enable or disable passes for single features.

## Data subpanel

### Combined

Deliver full combined RGBA Buffer.

### Z

Deliver Z Value pass.

### Mist

Deliver Mist factor pass. 0.0 to 1.0

### Normal

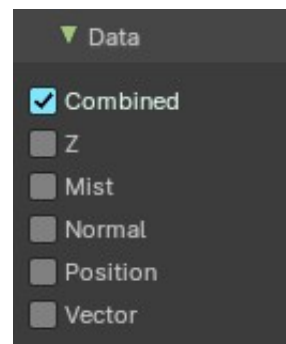

Deliver Normal pass.

### Position

Deliver Position pass.

### Vector

Deliver Vector pass.

## Light subpanel

### Diffuse

#### *Light*

Deliver diffuse direct pass.

#### *Color*

Deliver diffuse color pass.

### Specular

#### *Light*

Deliver specular direct pass.

#### *Color*

Deliver specular color pass.

## Volume

### *Light*

Deliver volume direct light pass.

## Other

### *Emission*

Deliver emission pass.

### *Environment*

Deliver environment lighting pass.

### *Shadow*

Deliver shadow pass.

### *Ambient Occlusion*

Deliver Ambient Occlusion pass. Ambient Occlusion needs to be enabled in the Render Properties.

### **Occlusion Distance**

Distance of object that contribute to the ambient occlusion effect.

### *Transparent*

Deliver alpha blended surfaces in a separate pass.

---

## Cryptomatte subpanel

Cryptomatte passes can be used to isolate objects or materials or assets in compositing.

### **Include**

#### *Object*

Render Cryptomatte Object Pass.

#### *Materials*

Render Cryptomatte Materials Pass.

#### *Asset*

Render Cryptomatte Asset Pass.

### **Include Settings**

These settings appears when you tick one of the above includes.

## Levels

How many unique objects can be distinguished per pixel.

**Note:** *Only active when you have something to include activated.*

## Shader AOV subpanel

AOV stands for Arbitrary Output Variables. Here you can add custom render passes for arbitrary shader node components. These values can then be used in the post processing in the node editor.

To use Shader AOVs create the pass in the Shader AOV panel then reference this pass with the AOV Output shading node. Each AOV in the list consists of a Name and Data Type.

## List of AOV

### Name

The name of the render pass. This is the Name that is referenced in the AOV Output node. You can name it as you like as long as the name does not conflict with enabled built-in passes.

### Data Type

Right clicking at the black triangle at the end will reveal the type menu.

Shader AOVs can either express a Color or a Value variable. The Color variable as the name suggest can be used for a color but also a normal value. A Value variable can be used for any single numerical value.

## Add AOV

Adds an AOV to the list.

## Remove AOV

Removes the selected AOV from the list.

## Passes Panel - Cycles

Here you enable or disable render passes for single features.

## Data subpanel

### Include

#### **Combined**

Deliver full combined RGBA Buffer.

#### **Z**

Deliver Z Value pass.

#### **Mist**

Deliver Mist factor pass. 0.0 - 1.0.

#### **Normal**

Deliver Normal pass.

#### **Vector**

Deliver Speed Vector pass.

#### **UV**

Deliver UV pass.

#### **Denoising Data**

Store the denoising feature passes and the noisy image.

### Indexes

#### **Object Index**

Deliver Object Index pass.

#### **Material Index**

Deliver Material Index pass.

### Debug

#### **Sample Count**

Number of samples/camera rays per pixel.

### Alpha Threshold

Z, Index, Normal, UV and Vector passes are just affected by surfaces with alpha transparency equal or higher this threshold.

## Mist subpanel

When you activate Mist pass, then the Mist Pass subpanel shows.

### Start

The starting distance of the mist, measured from the camera.

### Depth

The distance over which the mist effect fades in.

### Falloff

The falloff progression of the mist.

---

## Light subpanel

### Diffuse

#### *Direct*

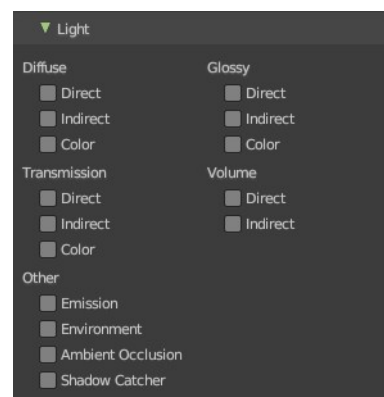

Deliver direct pass.

#### *Indirect*

Deliver indirect pass.

#### *Color*

Deliver color pass.

### Glossy

#### *Direct*

Deliver direct pass.

#### *Indirect*

Deliver indirect pass.

#### *Color*

Deliver color pass.

---

## **Transmission**

### ***Direct***

Deliver direct pass.

### ***Indirect***

Deliver indirect pass.

### ***Color***

Deliver color pass.

---

## **Volume**

### ***Direct***

Deliver direct pass.

### ***Indirect***

Deliver indirect pass.

### ***Color***

Deliver color pass.

---

## **Other**

### ***Emission***

Deliver Emission pass.

### ***Environment***

Deliver Environment pass.

### ***Ambient Occlusion***

Deliver Ambient Occlusion pass.

### ***Shadow Catcher***

Pass containing light and shadows that you want to multiply into the background image.

---

## Cryptomatte subpanel

Cryptomatte passes can be used to isolate objects or materials or assets in compositing.

### Include

#### *Object*

Render Cryptomatte Object Pass.

#### *Materials*

Render Cryptomatte Materials Pass.

#### *Asset*

Render Cryptomatte Asset Pass.

### Include Settings

These settings appears when you tick one of the above includes.

#### *Levels*

How many unique objects can be distinguished per pixel.

#### *Accurate Mode*

Generate a more accurate cryptomatte pass. This feature renders at the CPU only, and consumes more memory.

## Shader AOV subpanel

AOV stands for Arbitrary Output Variables. Here you can add custom render passes for arbitrary shader node components. These values can then be used in the post processing in the node editor.

To use Shader AOVs create the pass in the Shader AOV panel then reference this pass with the AOV Output shading node. Each AOV in the list consists of a Name and Data Type.

### List of AOV

#### *Name*

The name of the render pass. This is the Name that is referenced in the AOV Output node. You can name it as you like as long as the name does not conflict with enabled built-in passes.

#### *Data Type*

Right clicking at the black triangle at the end will reveal the type menu.

Shader AOVs can either express a Color or a Value variable. The Color variable as the name suggest can be used for a color but also a normal value. A Value variable can be used for any single numerical value.

## Add AOV

Adds an AOV to the list.

## Remove AOV

Removes the selected AOV from the list.

## Light Groups sub panel

Light groups are a type of pass that only contains light render data from a subset of light sources and their influences. This is useful to set light sources to affect only specific objects in a scene.

Light Groups passes are created in the View Layer tab then light sources and influences are assigned to individual passes in the Object tab in the Light Option panel of the light source and objects.

Any light source (lamps, objects with emission materials and/or the environment) can be assigned to light groups.

To assign a light source to a Light Pass, use the Light Options panel in the Object tab of the light source.

**Note:** *Light groups are identified by name - therefore the name of the Light Group in the View Layer and the name that is set in and Light Source Light Options must match for them to be included in the Light Group pass.*

## Add Light Group

Adds a new light group to the list.

## Remove Light Group

Removes the selected lightgroup from the list.

## Lightgroup Sync menu

### **Add used Light groups**

Add all assigned light sources with light groups to the list. Sometimes there are objects that are assigned to a light group which are not in the list yet – typical when appended objects from another file, as an example.

### **Remove unused light groups**

Removes all light groups from the list that has no user.

## Light Options – Object Properties Tab

With light linking and Light Group passes, light sources can be set to affect only specific objects in the scene in the Object tab > Light Options panel.

**Note:** *Objects must be have an emission material to have an influence in the Light Group.*

### Light Group

Here you assign the light source to a Light Group.

### Light Linking

Here you create and assign a Light Linking group to objects and collections. This assists in including or excluding objects from a lights influence. Default assignment of a Light Group will influence everything in the scene.

**Note:** *Consider this as an exclusive override object and collection influence of an emission object or light source.*

### New Light Linking Collection

Creates a new empty Light Linking collection. Here you can drag and drop objects and collections for object and collection overrides.

### Collection Drop Down Selector

Selects an existing collection as the Light Linking influence of the Light Group.

### Remove Collection

Removes the collection from the Light Group

### Light Linking List

This list shows the objects and collections in the assigned Light Linking influence collection.

### Toggle object Light Influence

Toggles the object influence or exclusion from the listed light group light

sources.

### Remove object from Collection

Removes the object from the listed light group collection. Keep in mind this will change collection order in the View Layer mode of the Outliner Editor.

**Note:** You can drag and drop any object or collection from the Outliner Editor into the light group list at any time. Keep in mind this changes collection order in the Outliner.

## Light Linking Sync Menu

### Select Light Linking Receivers

Selects all object light influences in the Light Linking list.

## Shadow Linking

Here you create and assign a Shadow Linking group with objects and collections. Shadow linking additionally gives control over which objects acts as a shadow blocker or shadow exception for the light sources of a light group.

### New Shadow Linking Collection

Creates a new empty collection. Here you can drag and drop objects and collections.

### Collection Drop Down Selector

Selects an existing collection as the influence of the Light Group.

### Remove Collection

Removes the collection from the Light Group

### Shadow Linking List

This list shows the objects and collections in the assigned Shadow Linking influence collection.

### Toggle object Light Influence

Toggles the object influence or exclusion from the listed light group light sources.

### Remove object from Collection

Removes the object from the listed light group collection. Keep in mind this will change collection order in the View Layer mode of the Outliner Editor.

**Note:** You can drag and drop any object or collection from the Outliner Editor into the light group list at any time. Keep in mind this changes collection order in the Outliner.

## Shadow Linking Sync Menu

### Select Light Linking Blockers

Selects all object shadow blockers in the Shadow Linking list.

## Filter Panel - Eevee

### Include

#### Environment

Render Sky in this layer.

#### Surfaces

Render solid surfaces in this layer.

#### Curves

Render Hair in this layer.

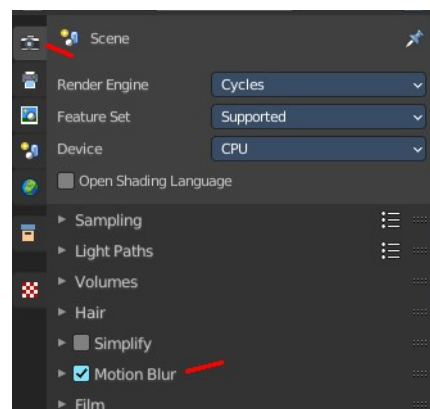

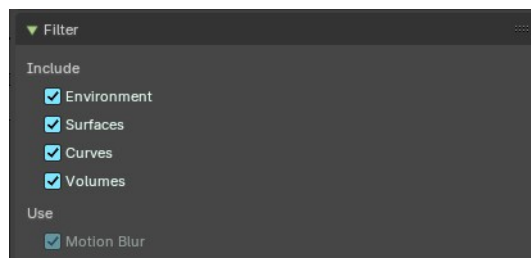

#### Volume

Render volumes in this layer.

### Use

#### Motion Blur

Render Motion Blur, if enabled in the scene.

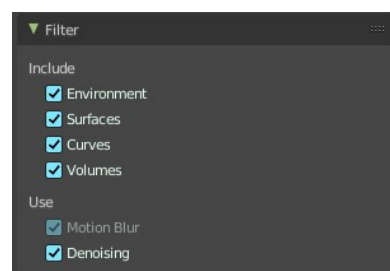

## Filter Panel - Cycles

### Include

#### Environment

Render Sky in this layer.

## Ambient Occlusion

Render Ambient Occlusion in this layer.

## Surfaces

Render solid surfaces in this layer.

## Curves

Render Hair in this layer.

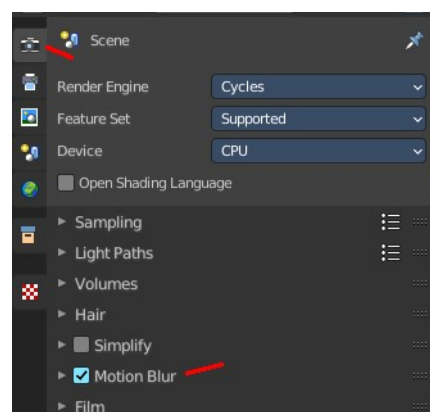

## Volume

Render volumes in this layer.

## Use

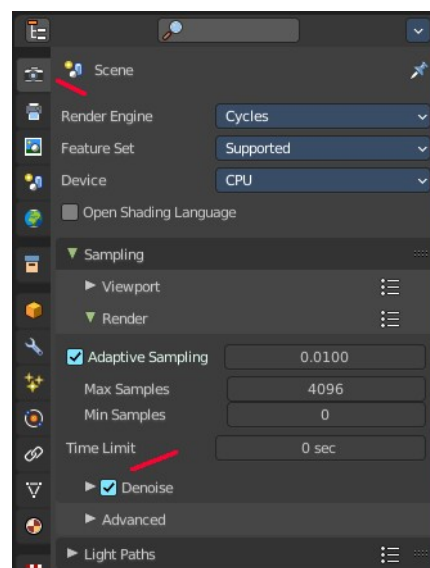

### Motion Blur

Render Motion Blur, if enabled in the scene.

### Denoising

Use Denoising, if enabled in the scene.

## Override Panel - Cycles

Here you can add a material that overrides all other materials in this layer. This allows clay renderings.

## Material Override

Pick a material in the scene that should override all other materials.

## Samples

Override number of render samples for this view layer. A value of 0 will use the scene setting values.

# Freestyle Panel

This panel and all further freestyle panels just shows when you have Freestyle activated in the Render Properties!

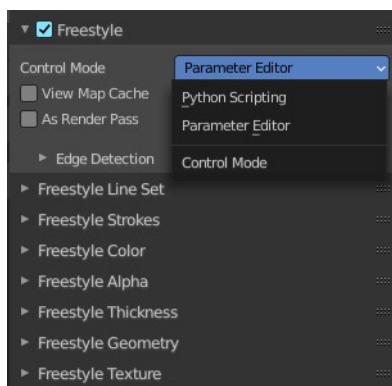

## Enable

Enables or disables the freestyle layer in the current view layer.

## Control Mode

You can either control the freestyle shapes by the settings in the panels. Or you can use a python script to define all the shapes. In this case the panels vanishes, and you can add your style script below.

## View Map Cache

Keep the computed Key Map. And avoid recalculation if mesh geometry is unchanged.

## As Render Pass

Renders the freestyle pass as a separate pass instead of adding it as an overlay to the Combined pass.

## Edge detection subpanel

How the edge detection happens.

### **Crease Angle**

Angular Threshold for detecting crease angles.

### **Culling**

Ignore edges that are out of view.

### **Face Smoothness**

Take the face smoothness into account for the view map calculation.

### **Material Boundaries**

Use Material Boundaries.

### **Ridges and Valleys**

Use ridges and valleys for the view map calculation.

### **Suggestive Contours**

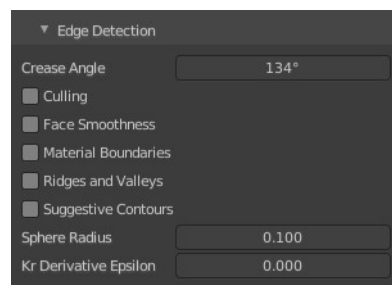

Use suggestive contours.

### **Sphere Radius**

The sphere radius for calculating curvatures

### **Kr Derivate Epsilon**

The Ki Derivate Epsilon radius for calculating suggestive contours.

## Style Module subpanel

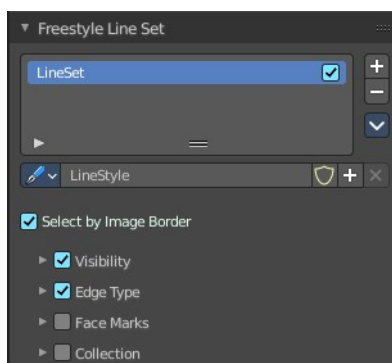

This panel appears with Control Mode Python Scripting. Add a python script that defines the style.

The structure of such a style is not defined nor described. Please ask the Blender developers.

# Freestyle Line Set Panel

The line set settings.

## List of Line Sets

A line set holds the line style. You can have more than one line set. But just one LineStyle per set.

The line sets can be activated or deactivated with the checkbox at the end.

## Drag Handler

Allows to resize the list.

## Search field

When you click at the triangle button then you can reveal a search field.

## *Edit Box*

Type in the search term and hit enter.

## *Invert*

Inverts the search.

## *Sort by Name*

Sorts the list by name

## *Reverse*

Reverts the list content.

## Add Line Set

Adds a new line set. Adding a new line set also adds a new LineStyle.

## Remove Line Set

Removes the selected line set.

## Lineset Specials menu

### *Copy Line Set*

Copies the currently selected line set and all its settings.

### *Paste Line Set*

Pastes the copied line set and all its settings into the currently selected line set.

## Move Line Set up or down

Moves the selected up or down in the list.

## Line style data property

### Data Browser

A list of available LineStyles.

### Edit Box

Displays the name of the currently active LineStyle. It also allows you to rename the LineStyle. Click into the edit box, change the name, hit enter.

### Fake User

Save this LineStyle with the scene even when it has no user. Fake User is an old Blender concept to keep data in the scene that has no user. Data without an user gets usually deleted with saving the scene.

### Add new LineStyle

Adds a new LineStyle.

### Remove LineStyle

This button is dysfunctional and permanently greyed out. Once added LineStyles are permanent by Blender design since every line set needs at least one linestyle. You can only remove unused linestyles by purging unused Data in the outliner.

## Select by Image Border

Select feature edges by image border.

## Visibility Subpanel

Determine how to use visibility for feature edge detection.

### Type

#### *Visible*

Select visible feature edges.

#### *Hidden*

Select hidden feature edges.

#### *Quantitative invisibility*

Select feature edges within a range of quantitative invisibility values. The

value is called QI.

### Start

The first value.

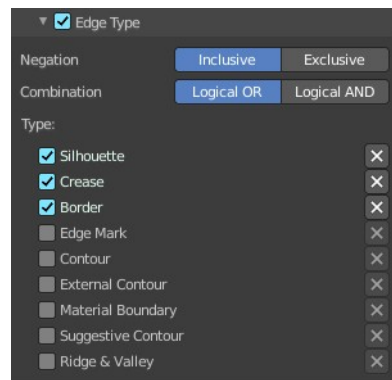

### End

The last value.

## Edge Type subpanel

### Selection by Edge Types

The checkbox in the header activates or deactivates the feature. Select feature edges based on Edge Types.

### Negation

#### *Inclusive*

Select edges by satisfying the selected options.

#### *Exclusive*

Select edges by satisfying the exact opposite of the selected options.

### Combination

#### *Logical Or*

Select edges by satisfying at least of the selected options.

#### *Logical And*

Select edges by satisfying all of the selected options.

### Type

What type to use. The names should be self explaining. The X Button at the end is to exclude this type instead of including it.

## Face Masks Subpanel

### Selection by Face Marks

Select Feature Edges by Face Marks.

### Negation

Include or exclude the edges selected by face marks.

### Condition

Select a feature edge if one face is marked. Or select a feature edge if the two adjacent faces are marked.

## Collection Subpanel

### Selection by Collection

Select feature edges based on a collection of objects.

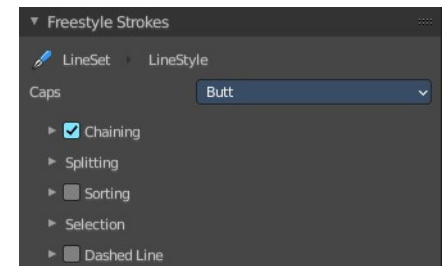

### Line Set Collection

Pick the collection that you want to use.

### Negation

Select feature edges by including or excluding the selected collection.

## Freestyle Strokes Panel

### Caps

Select the shape of both ends of the stroke. Butt, Round or Square.

## Chaining Subpanel

### Chaining

Enable chaining of feature edges.

### Method

How feature edges are jointed to form chains.

#### *Plain*

Feature edges are jointed plain.

#### *Sketchy*

Feature edges are jointed sketchy.

## Rounds

Number of rounds in a sketchy multiple touch.

---

## Splitting subpanel

### Min 2D Angle

Minimum 2d angle for splitting chains.

### Max 2D Angle

Maximum 2d angle for splitting chains.

### 2D Length

Curvilinear length for 2d splitting

### Material Boundary

Split chains of feature edges at material boundaries.

## Split Pattern sub subpanel

### Use Split Pattern

Enable chain splitting by dashed line patterns.

### Dash 1, 2, 3

Length of the dashes for splitting.

### Gap 1, 2, 3

Length of the gaps for splitting.

## Sorting subpanel

### Sort Key

How to determine the stacking order of chains.

## Integration Type

How the sort key is computed for each chain.

## Sort order

Sort by default or inverse.

## Selection Subpanel

### Min 2D Length

The selection of chains by a minimum 2D length.

### Max 2D Length

The selection of chains by a maximum 2D length.

### Chain Count

Select first N chains. N stands for a variable, and is defined in the edit box.

## Dashed Line subpanel

### Dashed Line

Enable dashed line. A line is then displayed as dashes.

### Dash 1, 2, 3

Length of the dash for the dashed lines.

### Gap 1, 2, 3

Length of the gap for the dashed lines.

## Freestyle Modifiers

The Freestyle panels Freestyle Color, Freestyle Alpha, Freestyle Thickness and Freestyle Geometry allows you to use so called modifiers. Modifiers allows you to modify these settings in several aspects.

Some modifier, like the along stroke modifier, does have the same name. But has here and there different functionality.

Color, Alpha and Thickness Modifier

## Header

From left to right.

### **Triangle button**

Open or close the modifier panel.

### **Edit Box**

Displays the name of the modifier. You can also rename it. Click into the edit box, change name and hit enter.

### **Use**

Enable the modifier.

### **Copy Modifier**

Copies the Modifier.

### **Move Modifier**

Moves the modifier up or down the list.

### **Remove Modifier**

Removes the modifier from the list.

## Color Ramp

The color, alpha and thickness modifiers all have a color ramp.

### **Controls**

+

Add a stop to your color ramp. The stop will be added after the selected one, in the middle to the next one.

-

Deletes the selected color stop from the list.

## Tools menu

### **Flip Color Ramp**

Flips the gradient, inverting the values of the color ramp.

### **Distribute Stops from Left**

Rearrange the stops so that every step has the same space to the right.

### **Distribute Stops Evenly**

Space between all neighboring stops becomes equal.

### **Eyedropper (pipette icon) E**

An Eyedropper to sample a color or gradient from the interface to be used in the color ramp.

### **Reset Color Ramp**

Resets the color ramp to its default state.

## Color Mode

### **RGB**

Blends color by mixing each color channel and combining.

### **HSV/HSL**

Blends colors by first converting to HSV or HSL, mixing, then combining again. This has the advantage of maintaining saturation between different hues, where RGB would de-saturate, this allows for a richer gradient.

## Interpolation

### **Ease**

Uses an Ease Interpolation for the color stops.

### **Cardinal**

Uses a Cardinal Interpolation for the color stops.

### **Linear**

Uses a Linear Interpolation for the color stops.

### **B-Spline**

Uses a B-Spline Interpolation for the color stops.

### **Constant**

Uses a Constant Interpolation for the color stops.

## Color Ramp

The color band. A click at one of the color stops makes it the active one. You can move the color stops by clicking at them and dragging them around.

## Active Color Stop elements

Adjust the active color stop.

### **Choose active color stop**

Choose the color stop by index.

### **Number of Stop**

The active color stop.

### **Pos**

The position and color of the active color stop. The range goes from 0.000 to 1.000.

## Freestyle Color panel

Modify the color of the stroke.

### **Base Color**

Here you can choose the base color that needs to be modified.

## Freestyle Color modifiers

### **Along Stroke**

Add a colorband along the stroke.

### **Blend Mode**

The color blend mode.

### **Influence**

The influence of the modifier.

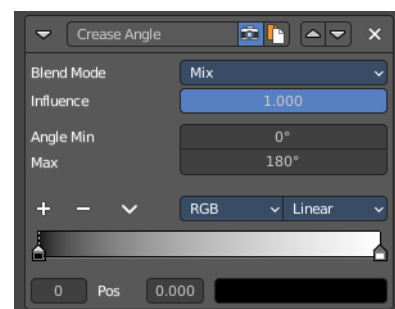

### **Crease Angle**

Add a color band along a crease angle. Which is the angle between two adjacent faces) If a stroke segment does not lie on a crease , then its properties are not touched by the modifier.

### **Blend Mode**

The color blend mode.

## Influence

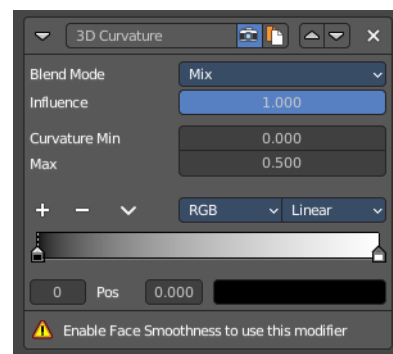

The influence of the modifier.

## Angle Min / Max

The minimum and maximum crease angle to modify thickness.

## Curvature 3D

This modifier is based on the radial curvatures of the underlying 3D surface. The curvature of a 2D curve at a point is a measure of how quickly the curve turns at the point. The quicker the turn is, the larger the curvature is at the point. The curvature is zero if the curve is a straight line. Radial curvatures are those computed for a 2D curve that appears at the cross section between the 3D surface and a plane defined by the view point (camera location) and the normal direction of the surface at the point.

This modifier requires to have the Face Smoothness option on and the object needs to have Smooth Shading.

## Blend Mode

The color blend mode.

## Influence

The influence of the modifier.

## Curvature Min and Max

The limits of the mapping. If the current point of the stroke is at Min Curvature or less from the target, it will take the start point of the mapping. If it is at Max Curvature or more from the target, it will take the end-point value of the mapping.

## Distance from Camera

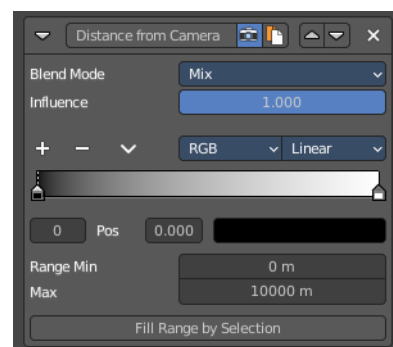

Recalculates the base property by the distance to the camera.

## Blend Mode

The color blend mode.

## Influence

The influence of the modifier.

## Range Min and Range Max

The minimum and maximum range. These values are in scene units.

## Fill Range by Selection

Sets the minimum and maximum range values from the distances between the current selected mesh vertices and the camera or the target.

---

## Distance from Object

Recalculates the base property by the distance to a chosen object.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

### Target

Pick the target object.

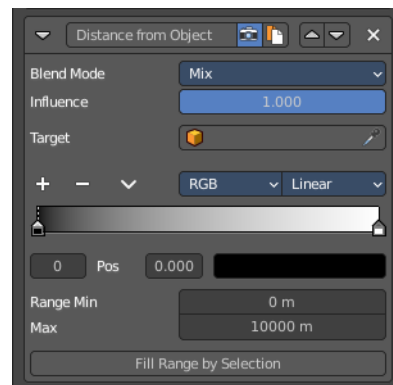

### Range Min and Range Max

The minimum and maximum range. These values are in scene units.

## Fill Range by Selection

Sets the minimum and maximum range values from the distances between the current selected mesh vertices and the camera or the target.

---

## Material

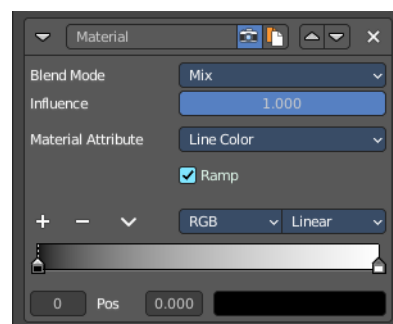

Alters the base property on the current material under the stroke.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

## Material Attribute

What attribute of the material under the stroke to alter.

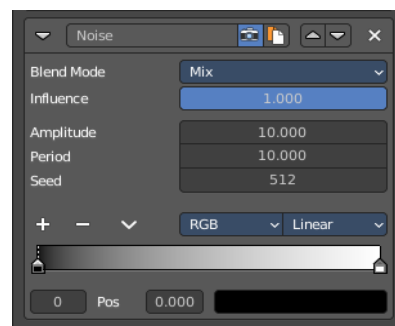

## Ramp

Shows and activates the color ramp.

## Noise

Uses a noise based pseudo random number generator to add some variation along the stroke.

## Blend Mode

The color blend mode.

## Influence

The influence of the modifier.

## Amplitude

The maximum value of the noise. A higher amplitude means a less transparent (more solid) stroke.

## Period

The period of the noise. This means how quickly the property value can change. A higher value means a more smoothly changing color along the stroke.

## Seed

Seed used by the pseudo-random number generator.

## Asymmetric

Thickness only – Allows the thickness to be distributed unevenly at every point.

## Tangent

Modifies the base value on the traveling direction of the stroke, evaluated at the stroke's vertices.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

## Freestyle Alpha panel

Modify the transparency of the stroke.

## Base Transparency

The base transparency that you want to modify.

## Freestyle Alpha modifiers

### Along Stroke

Add a gradient along the stroke.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

### Mapping

The mapping type. Linear or Curve.

### Invert

Inverts the values.

## Crease Angle

Add a gradient along a crease angle. Which is the angle between two adjacent faces) If a stroke segment does not lie on a crease , then its properties are not touched by the modifier.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

### Angle Min / Max

The minimum and maximum crease angle to modify thickness.

### Mapping

The mapping type. Linear or Curve.

### Invert

Inverts the values.

## Curvature 3D

This modifier is based on the radial curvatures of the underlying 3D surface. The curvature of a 2D curve at a point is a measure of how quickly the curve turns at the point. The quicker the turn is, the larger the curvature is at the point. The curvature is zero if the curve is a straight line. Radial curvatures are those computed for a 2D curve that appears at the cross section between the 3D surface and a plane defined by the view point (camera location) and the normal direction of the surface at the point.

This modifier requires to have the Face Smoothness option on and the object needs to have Smooth Shading.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

### Mapping

The mapping type. Linear or Curve.

## Invert

Inverts the values.

## Curvature Min and Max

The limits of the mapping. If the current point of the stroke is at Min Curvature or less from the target, it will take the start point of the mapping. If it is at Max Curvature or more from the target, it will take the end-point value of the mapping.

---

## Distance from Camera

Recalculates the base property by the distance to the camera.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

### Mapping

The mapping type. Linear or Curve.

### Invert

Inverts the values.

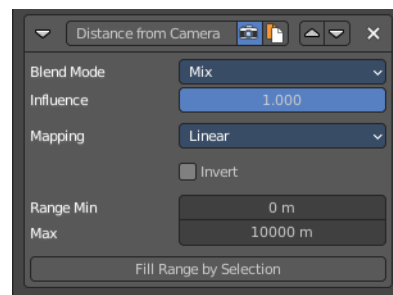

### Range Min and Range Max

The minimum and maximum range. These values are in scene units.

### Fill Range by Selection

Sets the minimum and maximum range values from the distances between the current selected mesh vertices and the camera or the target.

---

## Distance from Object

Recalculates the base property by the distance to a chosen object.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

## Target

Pick the target object.

## Mapping

The mapping type. Linear or Curve.

## Invert

Inverts the values.

## Range Min and Range Max

The minimum and maximum range. These values are in scene units.

## Fill Range by Selection

Sets the minimum and maximum range values from the distances between the current selected mesh vertices and the camera or the target.

## Material

Alters the base property on the current material under the stroke.

## Blend Mode

The color blend mode.

## Influence

The influence of the modifier.

## Material Attribute

What attribute of the material under the stroke to alter.

## Mapping

The mapping type. Linear or Curve.

## Invert

Inverts the values.

---

## Noise

Uses a noise based pseudo random number generator to add some variation along the stroke.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

### Amplitude

The maximum value of the noise. A higher amplitude means a less transparent (more solid) stroke.

### Period

The period of the noise. This means how quickly the property value can change. A higher value means a more smoothly changing color along the stroke.

### Seed

Seed used by the pseudo-random number generator.

### Mapping

The mapping type. Linear or Curve.

### Invert

Inverts the values.

---

## Tangent

Modifies the base value on the traveling direction of the stroke, evaluated at the stroke's vertices.

### Blend Mode

The color blend mode.

## Influence

The influence of the modifier.

## Mapping

The mapping type. Linear or Curve.

Linear  
Curve  
Mapping

## Invert

Inverts the values.

# Freestyle Thickness panel

Modify the thickness of the stroke.

## Base Thickness

The base thickness that you want to modify.

## Thickness Position

The thickness position of silhouettes and border edges.

### Center

Silhouettes and border edges are centered along the stroke.

### Inside

Silhouettes and border edges are drawn inside of the stroke.

### Outside

Silhouettes and border edges are drawn outside of the stroke.

### Relative

Silhouettes and border edges are shifted by a user defined thickness ratio.

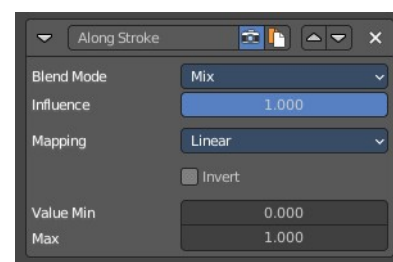

## **Thickness Ratio**

The thickness ratio to shift the silhouettes and border edges.

## Freestyle Thickness modifiers

### Along Stroke

Add a gradient along the stroke.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

### Mapping

The mapping type. Linear or Curve.

### Invert

Inverts the values.

### Value Min / Max

Minimum and maximum output value.

### Calligraphy

Generates different thickness, based on the orientation of the stroke. The result is a stroke thickness that orients at calligraphy.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

### Orientation

The angle of the virtual drawing tool, based at the vertical axis of the image. The thickest strokes will align with this angle.

### Thickness Min / Max

Minimum and maximum output value.

## Crease Angle

Add a gradient along a crease angle. Which is the angle between two adjacent faces) If a stroke segment does not lie on a crease , then its properties are not touched by the modifier.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

### Thickness Min / Max

The minimum and maximum thickness.

### Angle Min / Max

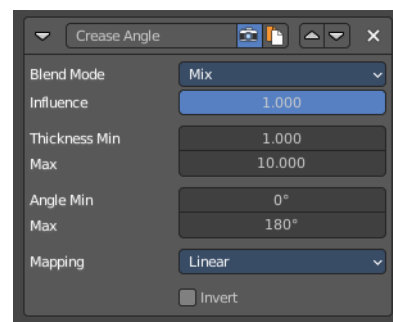

The minimum and maximum crease angle to modify thickness.

### Mapping

The mapping type. Linear or Curve.

### Invert

Inverts the values.

## Curvature 3D

This modifier is based on the radial curvatures of the underlying 3D surface. The curvature of a 2D curve at a point is a measure of how quickly the curve turns at the point. The quicker the turn is, the larger the curvature is at the point. The curvature is zero if the curve is a straight line. Radial curvatures are those computed for a 2D curve that appears at the cross section between the 3D surface and a plane defined by the view point (camera location) and the normal direction of the surface at the point.

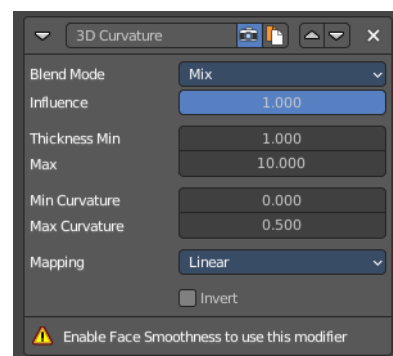

This modifier requires to have the Face Smoothness option on and the object needs to have Smooth Shading.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

## Thickness Min / Max

The minimum and maximum thickness.

## Curvature Min and Max

The limits of the mapping. If the current point of the stroke is at Min Curvature or less from the target, it will take the start point of the mapping. If it is at Max Curvature or more from the target, it will take the end-point value of the mapping.

## Mapping

The mapping type. Linear or Curve.

## Invert

Inverts the values.

## Distance from Camera

Recalculates the base property by the distance to the camera.

## Blend Mode

The color blend mode.

## Influence

The influence of the modifier.

## Mapping

The mapping type. Linear or Curve.

## Invert

Inverts the values.

## Range Min and Range Max

The minimum and maximum range. These values are in scene units.

## Value Min and Value Max

The minimum and maximum output value of the mapping. These values are in scene units.

## Distance from Object

Recalculates the base property by the distance to a chosen object.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

### Target

Pick the target object.

### Mapping

The mapping type. Linear or Curve.

### Invert

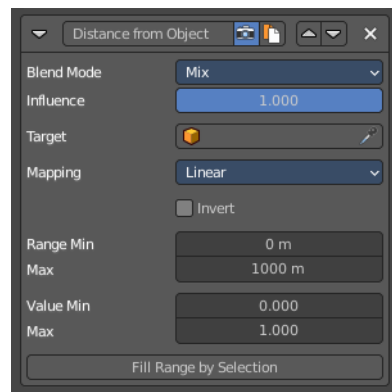

Inverts the values.

### Range Min and Range Max

The minimum and maximum range. These values are in scene units.

### Value Min and Value Max

The minimum and maximum output value of the mapping. These values are in scene units.

## Material

Alters the thickness of the stroke based on the current material under the stroke.

### Blend Mode

The color blend mode.

### Influence

The influence of the modifier.

## Material Attribute

What attribute of the material under the stroke to alter.

## Mapping

The mapping type. Linear or Curve.

## Invert

Inverts the values.

## Value Min and Value Max

The minimum and maximum output value of the mapping. These values are in scene units.

---

## Noise

Uses a noise based pseudo random number generator to add some variation along the stroke.

## Blend Mode

The color blend mode.

## Influence

The influence of the modifier.

## Amplitude

The maximum value of the noise. A higher amplitude means a less transparent (more solid) stroke.

## Period

The period of the noise. This means how quickly the property value can change. A higher value means a more smoothly changing color along the stroke.

## Seed

Seed used by the pseudo-random number generator.

## Asymmetric

Assign the thickness asymmetrical at both sides of the stroke.

## Tangent

Modifies the base value on the traveling direction of the stroke, evaluated at the stroke's vertices.

## Blend Mode

The color blend mode.

## Influence

The influence of the modifier.

## Thickness Min / Max

The minimum and maximum thickness.

## Mapping

The mapping type. Linear or Curve.

## Invert

Inverts the values.

## Freestyle Geometry

Modify the geometry of the freestyle strokes.

The modifier Sampling is on by default.

## Freestyle Geometry Modifiers

## 2D Offset

Offset the stroke vertices from its original position.

## Start / End

The start and end of the offset relative to the stroke.

## X / Y

The offset amount along X and Y axis of the stroke vertices.

---

## 2D Transform

Scale the stroke.

### Pivot

What center point to use for the scaling.

### Scale X / Y

The scale amount along X and Y.

### Rotation Angle

Rotate the stroke

---

## Backbone Stretcher

Stretch the stroke.

### Backbone Length

Amount of backbone stretching.

---

## Bezier Curve

Turn the stroke into a bezier curve.

### Error

The maximal allowed distance between the new bezier curve and the original backbone geometry.

---

## Blueprint

Turn the strokes into a blueprint/cad like style stroke.

### Shape

The shape of the blueprint contour strokes.

## Rounds

Number of rounds in contour strokes.

## Random Radius

Randomness of the radius.

## Center

Randomness of the center.

---

## Guiding Lines

Replaces a stroke by straight lines that connects both of its ends.

## Offset

Add an offset to the the start and end points along the original stroke, before generating the new straight one.

---

## Perlin Noise 1D

Adds one-dimensional Perlin noise to the stroke. This modifier will give an identical result for two strokes with the same length and sampling interval.

## Frequency

How dense the noise is (kind of a scale factor along the stroke).

## Amplitude

How much the noise distorts the stroke in the Angle direction.

## Seed

The seed of the random generator (the same seed over a stroke will always give the same result).

## Octaves

The “level of detail” of the noise.

## Angle

In which direction the noise is applied (0.0 is fully horizontal).

## Perlin Noise 2D

Adds one-dimensional Perlin noise to the stroke. Different to the Perlin Noise 1D modifier the modifier generates noisy displacements using 2D coordinates of stroke vertices as the input of the noise generator.

### Frequency

How dense the noise is (kind of a scale factor along the stroke).

### Amplitude

How much the noise distorts the stroke in the Angle direction.

### Seed

The seed of the random generator (the same seed over a stroke will always give the same result).

### Octaves

The “level of detail” of the noise.

### Angle

In which direction the noise is applied (0.0 is fully horizontal).

---

## Polygonization

Simplify the stroke.

### Error

The maximum distance allowed between the new simplified stroke and the original stroke.

---

## Sampling

Changes the definition and precision of the stroke for the following modifiers.

### Sampling

The smaller this value, the more precise are the strokes. The computation of smaller values needs more memory and time.

---

## Simplification

Simplify the stroke by merging stroke vertices that are close to each other.

## Tolerance

How close the vertices need to be to each other to be merged.

---

## Sinus Displacement

Adds a sinusoidal displacement to the stroke.

### Wavelength

How wide the undulations are along the stroke.

### Amplitude

How high the undulations are across the stroke.

### Phase

Allows “offsetting” (“moving”) the undulations along the stroke.

Tip! With a phase of 0 the undulations this modifier produces look exactly the same at a Phase of 0. Same goes for any positive or negative multiple of the Wavelength set on the modifier. This allows you to render short video sequences with wavy lines that can then be seamlessly looped without any visual jumps in the undulations along the line.

---

## Spatial Noise

Adds some spatial noise to the stroke. Spatial noise displacements are added in the normal direction of each stroke vertex.

### Amplitude

How much the noise distorts the stroke.

### Scale

How wide the noise is along the stroke.

### Octaves

The level of detail of the noise.

### Smooth

When enabled, apply some smoothing over the generated noise.

### Pure Random

The usual noise is not really random. Each value depends of the value before. So as a result is more a series of

values. Which can lead to patterns. Pure random adds much more randomness to the strokes.

## Tip remover

Removes a part of the stroke at the start and the end of a stroke

## Tip Length

The length of the stroke that you want to remove.

## Freestyle Texture

You can use a texture for the freestyle lines. The texture is created and managed in the texture tab. The material is created and managed in the Shader editor.

In this panel you just manage some settings for it

## Use Nodes

Use shader nodes for the line style.

## Spacing along Stroke

The spacing for textures along stroke length

## Go to Linestyle Texture Properties

Switch to the Texture Properties tab to create and manage the texture.

## Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

## Add

Adds a new property.

## Edit

Opens a panel where you can adjust the settings for the custom property.

## Remove

Removes the property.

## Scene Tab

Scenes are a way to organize your work. Usually you work with just one scene. But each .blend file can contain multiple scenes which share other data, such as objects and materials.

The scenes can be managed in the scene drop down box up right in the header.

Appending happens through the File menu / Append.

## Render Engine

Shows the active render engine. Specific renderers do have other settings. And you can also switch to another renderer. But note that this is more a visual guide. It misses the Cycles render settings.

## Scene Panel

### Scene Data Prop

A list of the available scenes.

### Scene Browser

A list of the available scenes.

### Edit Box

The name of the currently active scene.

### Pin Scene to Workspace

Allows you to pin this particular scene to a workspace. So that this scene gets loaded when you enter this workspace.

### New Scene

Creates a new scene. It will call a sub menu where you can choose with what settings you want to initialize the new scene.

### *New*

Creates an empty scene with default values.

### *Copy Settings*

Creates an empty scene but also copies the settings from the active scene into the new one.

### *Linked Copy*

This option creates a new scene with the same settings and contents as the active scene. However, instead of copying the objects, the new scene contains links to the objects in the old scene. Therefore, changes to objects in the new scene will result in the same changes to the original scene, because the objects used are literally the same. The reverse is also true.

## Full Copy

Using this option, nothing is shared. This option creates a fully independent scene with copies of the active scenes contents. Every object in the original scene is duplicated, and a duplicate, private copy of its object-data is made as well.

### Note

To choose between these options, it's useful to understand the difference between *Objects* and *Object Data*. See *Duplication*.

The choices for adding a scene, therefore determine just how much of this information will be *copied from* the active scene to the new one, and how much will be *shared* (linked).

## Duplicate4

Dysfunctional in this context.

## Delete Scene

Deletes the currently selected scene.

## Camera

Here you can define the active camera for rendering.

## Background Scene

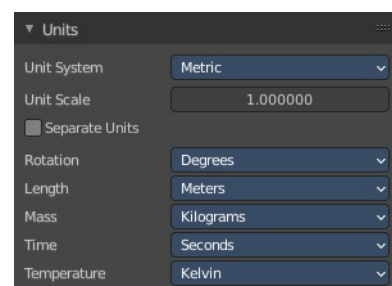

Here you can choose a background scene.

## Active Movie Clip

Here you can choose an active movie clip for constraints and viewport drawing.

## Units Panel

Here you define the units for the scene.

## Unit System

The overall unit system that gets used.

## Unit Scale

The standard unit scale.

## Separate Units

Display Units in pairs.

## Rotation

Units to display on rotation. Radians or Degree.

## Length

Units to display the length values.

## Mass

Units to display the mass values.

## Time

Units to display Time values.

## Temperature

Units to display temperature.

## Gravity Panel

Here you can adjust the gravity settings. The default values are the standard gravity than on earth with the usual acceleration of 9.81 meters per second in Z direction.

Gravity is used for physics simulations like rigid body.

## Enable

In the header is a checkbox to enable the gravity.

## Gravity X, Y Z

The gravity values.

## Animate Property

These properties can be animated. Activating this button sets a keyframe.

## Simulation Panel

### Simulation Range

Allows you to use a simulation range that is different from the scene range for simulation nodes that don't override the frame range themselves.

### Start

The start frame for the simulation.

### End

The end frame for the simulation.

## Keying Sets Panel

Keying Sets are a collection of properties. They are used to keyframe multiple properties at the same time.

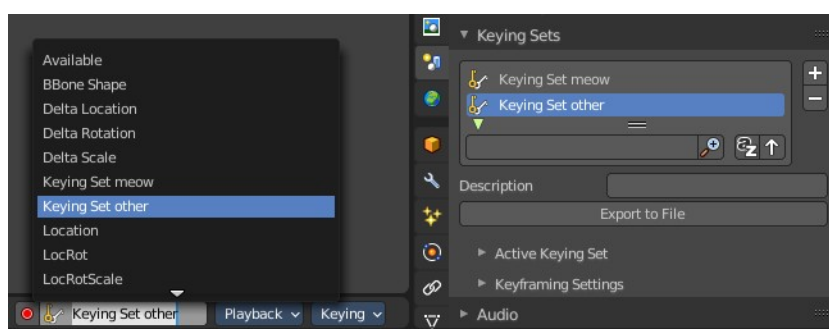

There are some built in Keying Sets, and also custom Keying Sets called *Absolute Keying Sets*.

This panel here is used to add, select and manage Absolute Keying sets.

When you add a custom keying set in the list box, then you will reveal further options.

Every keying set that you add here is also available in the list of active keying sets in

the header of the timeline editor.

## Keying Set List

Here you can see the list of your Absolute Keying Sets. The active keying set is highlighted in blue.

It has a search form below the list. Click the arrow button down left to expand the search.

The list display can be resized by clicking at the dotted area and drag it up or down.

## Add / Remove Keying Set

At the right side you can add or remove a keying set with the + and - buttons

## Description

Here you can add a description to your keying set.

## Export to file

Here you can export the keying set to a Python file.

To re add the keying set from the *File.py*, open then run the *File.py* from the Text Editor.

## Active Keying Set

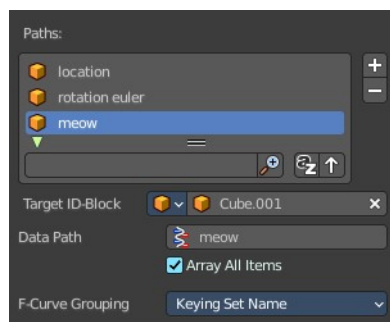

Here you can add properties to the active keying set.

### Paths

A list with a collection of *Paths* each with a *Data Path* to a property to add to the active Keying Set. The active *Path* is highlighted in blue.

It has a search form below the list. Click the arrow button down left to expand the search.

The list display can be resized by clicking at the dotted area and drag it up or down.

## Add / Remove Paths

At the right side you can add or remove a keying set with the + and - buttons

## Target ID Block

Set the *ID-Type* + *Object ID Data Path* for the property. Means pick the object or data type that you want to influence here. When it is a mesh object then you should choose mesh here.

At the left you have a list of the available ID Types. At the right you have a picker as long as you haven't defined the object where you want to use this property at. Use this picker to pick up the object.

Or choose your mesh object from the list of scene objects.

## Data Path

Here you can assign a data path variable. This variable points to a python animation property that can be used for the mesh object. Location or rotation euler are valid terms for a mesh object. meow not. It will simply not work. For the available properties for the different object types please have a look in the python API.

## Array all Items

For an Array / Vector type, use *All Items* from the *Data Path* or select the array index for a specific property.

## FCurve Grouping

This controls what *Group* to add the *Channels* to. *Keying Set Name*, *None*, *Named Group*.

## Keyframe Settings

General Override and Active Set Override have the same items each. General override works for all keying sets. Active sets just overrides the current active keying set.

The check boxes activates the item to make it available. The buttons behind sets the item on or off.

## Only Needed

Only insert keyframes where they're needed in the relevant F-Curves.

## Visual Keying

Insert keyframes based on the visual transformation.

## XYZ=RGB Colors

For new F-Curves, set the colors to RGB for the property set, Location XYZ for example.

## Audio Panel

Here you can adjust the general audio settings.

### Volume

The Audio Volume.

### Animate Property

This property can be animated. Clicking at the button will set a keyframe at the current frame position.

### Distance Model

The algorithm for attenuation calculation.

### Doppler Speed

Speed of sound for Doppler effect calculation.

### Doppler Factor

Pitch factor for Doppler effect calculation.

### Update Animation Cache

Update the audio animation cache. Something that you might want to do after changes at the settings.

## Rigid Body World Panel

The rigid body world is a group of Rigid Body objects, which holds settings that apply to all rigid bodies in this simulation.

When you add Rigid Body physics on an object, primary there is created a group of objects with default “RigidBodyWorld” name. Rigid body objects automatically are added to this group when you add Rigid Body physics for them.

You can create several Rigid Body World groups, and allocate the Rigid Body objects with Groups panel in Object context.

Rigid body objects and constraints are only taken into account by the simulation if they are in the groups specified in Group field of the Rigid Body World panel in the Scene context.

## Activate

In the header is a checkbox where you can enable or disable the Rigid Body World.

## ***Activate / Remove Rigid Body World***

Activate or Remove Rigid Body simulation from the current scene.

---

## Settings

A sub menu with further settings.

## Animate Property

The properties with an animate property at the right can be animated. Clicking at the button will set a keyframe at the current frame position.

## Collection

Containing rigid body objects participating in this simulation.

## Constraints

Containing rigid body object constraints participating in the simulation.

## Speed

Can be used to speed up/slow down the simulation.

## Split Impulse

Enable/disable reducing extra velocity that can build up when objects collide (lowers simulation stability a little so use only when necessary). Limits the force with which objects are separated on collision, generally produces nicer results, but makes the simulation less stable (especially when stacking many objects).

## Steps Per Second

Number of simulation steps made per second (higher values are more accurate but slower). This only influences the accuracy and not the speed of the simulation.

## Solver Iterations

Amount of constraint solver iterations made per simulation step (higher values are more accurate but slower). Increasing this makes constraints and object stacking more stable.

## Cache

A sub menu with cache settings. The cache is getting used for animation.

## Simulation Start / End

First and last frame of the simulation.

## Bake

Calculates the simulation and protects the cache. You need to be in Object mode to bake.

## Calculate to Frame

Bake physics to current frame.

## Current Cache to Bake

Bake from Cache.

## Bake All Dynamics

Bake all physics.

## Free All Bakes

Free all baked caches of all objects in the current scene.

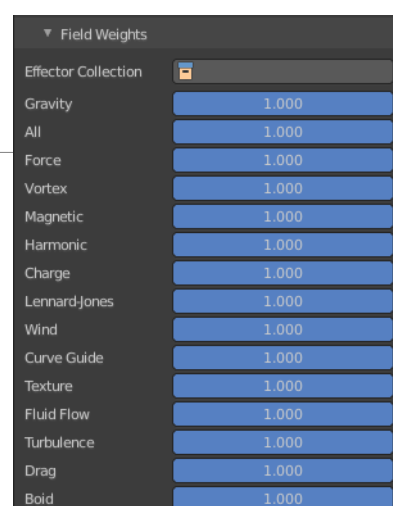

## Update All To Frame

Update cache to current frame.

If you haven't saved the blend file, the cache is created in memory, so save your file first or the cache may be lost.

## Field Weights

With force fields you can influence rigid body objects in physics simulations. Every force field has its own local settings, which can be adjusted in the

physics panel. Here you can adjust the general field weights for those forces.

## Custom Properties Panel

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

### Add

Adds a new property.

### Edit

Opens a panel where you can adjust the settings for the custom property.

### Remove

Removes the property.

## World Tab

The world tab provides you with world settings. Like Viewport Display color. The content vary, dependent of the chosen renderer.

## Render Engine

Shows the active render engine. Specific renderer does have other settings. And you can also switch to another renderer. But note that this is more a visual guide. It misses the Cycles render settings.

## World Data Prop

Here you can manage and change your world settings. There can be more than one World.

## World Browser

Here you can see and choose your world files.

## World Edit Box

Here you can see and change the name of the current world file.

## Fake User

When enabled then this world file will be stored internally. And will remain in the scene.

## New

Create a new world file.

## Remove

Note that this just sets the World file inactive. It is still in the list. You can delete the world file when it has no user anymore by saving the scene, closing and reopening Bforartists.

## Viewport Display - Cycles, Workbench

### Color

The color that you can choose here is the background color for rendering the image.

### Animate Property

This property can be animated. Activating this button sets a keyframe.

## Viewport Display - Eevee

### Color

The color that you can choose here is the background color for rendering the image.

### Animate Property

This property can be animated. Activating this button sets a keyframe.

## Jittered Shadows

Enable jittered soft shadows to increase precision in the viewport. Note that this feature has a big performance impact.

## Custom Properties Panel - All Renderers

Here you can define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

## Add

Adds a new property.

## Edit

A panel where you can adjust the settings for the custom property.

## Remove

Removes the property.

# Surface Panel - Eevee and Cycles

## Use Nodes

Use Nodes or simple background color.

When you use Nodes then you will reveal further options.

Note that Cycles misses the Use Nodes button once you have activated the nodes.

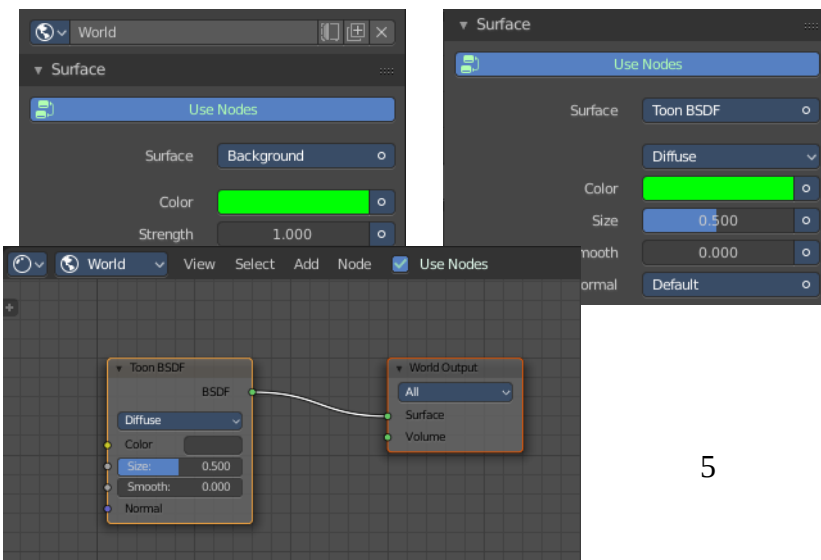

## Color without nodes

The color that you can choose here is the background color for rendering the image.

## Surface

Here you can choose what shader you want to use for the background. Usually the Background shader. But you can use any shader in the list here too.

The options below changes dependent of the shader that you choose. They are explained in the shader editor chapter.

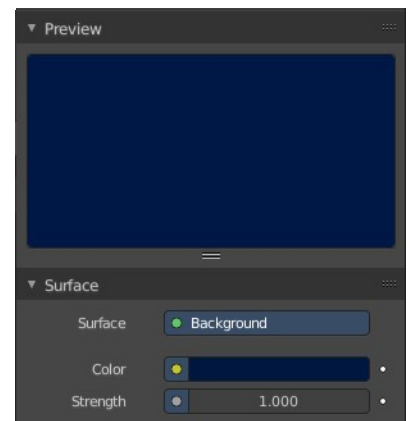

## Cycles - Preview Panel

The Preview panel gives you a preview of the background color.

The color can also be an image. This depends of what you have chosen for the color method in the surface panel.

## Eevee and Cycles - Volume Panel

Volume rendering is a method to render light as it passes through a media within a 3D region. Here you can choose a shader for volume rendering.

## Cycles - Ray Visibility Panel

Adjust the ray visibility.

### Camera

Object Visibility for Camera rays.

## Diffuse

Object Visibility for Diffuse Reflection rays.

## Glossy

Object Visibility for Glossy Reflection rays.

## Transmission

Object Visibility for Transmission rays.

## Volume Scatter

Object Visibility for Volume Scatter rays.

# Cycles - Settings Panel

## Surface

### Sampling

Here you can choose the method for the surface sampling.

### Map Resolution

Just with method manual. Adjust the map resolution manually.

### Max Bounces

Maximum number of bounces the background light will contribute to the render.

### Shadow Caustics

Generate caustics in the shadows of refractive surfaces.

## Volume

### Sampling

Here you can choose the volume sampling method.

### Interpolation

Here you can choose between cubic and linear interpolation.

### Homogeneous

When using volume rendering, assume that the volume has the same density everywhere.

### Step Size

Distance between volume shader samples when rendering the volume. Lower values increases accuracy and render time.

## Light Group subpanel

Manage the light groups that you want to use in the world settings.

Light group allows you to save light settings into layers. This enables you to adjust the lighting afterwards in compositing for example.

You need to have a lightgroup in the scene. You create them in the View Layer Properties tab in the Passes panel in the Light Grups subpanel.

## Cycles - Ray Visibility Panel

Adjust the ray visibility.

### Camera

Object Visibility for Camera rays.

### Diffuse

Object Visibility for Diffuse Reflection rays.

### Glossy

Object Visibility for Glossy Reflection rays.

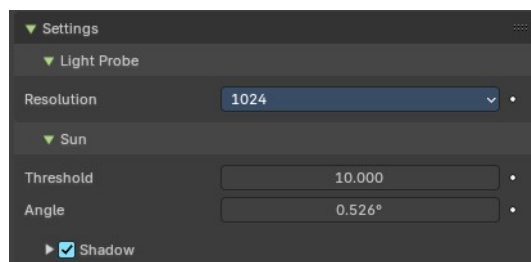

## Transmission

Object Visibility for Transmission rays.

## Volume Scatter

Object Visibility for Volume Scatter rays.

## Eevee - Settings Panel

## Light Probe subpanel

### Resolution

The resolution when baked to a texture.

## Sun subpanel

### Threshold

The maximum value of the world contribution that will be recorded inside the light probe. The excess contribution is converted to a sunlight. A value of zero disables the feature.

### Angle

Angular diameter of the sun as seen from the earth.

## Shadow subpanel

### Shadow

Enable sun shadow casting.

## **Jittered Shadows**

Enable jittered soft shadows to increase precision in the final rendering. Note that this feature has a big performance impact.

### ***Overblur***

Apply shadow tracing to each jittered sample to reduce under-sampling artifacts.

### **Filter**

Blur shadow antialiasing.

### **Resolution Limit**

Maximum size of a shadow map pixel. Lower values gives higher resolution and better quality.

## Collection Properties Tab

The world tab provides you with collection related settings.

## Restrictions Panel

Set restrictions for the selected collection(s).

### Selectable

Make this collection and its content selectable.

### Disable in Renders

Don't render this collection and its content.

### Holdout

Mask out objects in collection from view layer.

### Indirect Only

Make the objects in the collection just contribute indirectly. By light or shadow or reflections.

## Instancing panel

### Instance Offset

Adjust an offset from the origin when instancing the collection.

## Exporters panel

This panel contains the collection settings to assign an exporter per collection, where you can batch export collections in multiple file formats.

**Note:** You can also batch export collections from the Topbar File header menu.

## Add

Adds an exporter operator to the collection. This will show an exporter icon on the collection in the outliner, and list the file format the collection will export to.

### File Exporter Types:

- Alembic
- USD (Universal Scene Description)
- OBJ (Wavefront Object)
- Stanford PLY
- FBX
- glTF 2.0

## Export All

Exports all the collections with exporter operators assigned.

## Exporter Operators

### Exporter Operator Presets

This will save exporter operator settings. Right now there are two entries for the same thing. One will be removed.

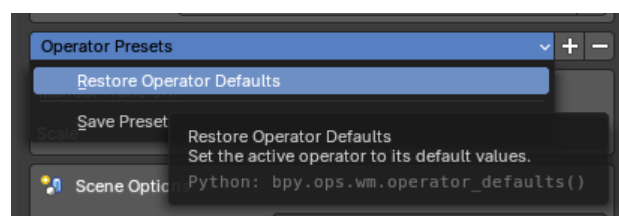

### List of available presets

The list of available presets. The string *\*Missing Paths\** indicates that no custom preset exists yet.

### Add Operator Preset

Adds a new operator preset. A popup dialog will appear

where you can give the new preset a name.

### **Presets Remove**

Removes a preset.

### **Remove Operator Preset**

Removes the active preset.

**Note:** *that you cannot display the current active preset. So choose it from the list, and then click at the remove operator.*

### **Export**

Export the individual collection.

### **Remove Exporter**

Remove the exporter operator from the collection.

### **File Path**

Defines the path for the exported file.

### **File Path**

The file path.

### **Browse File Path**

Open and browse for the file path.

### **Exporter Operator Properties**

These are the same properties from the file type export properties.

## **Line Art Panel**

### **Usage**

The method to display the line art in this collection.

## Include

Generate feature lines for this collection.

## Occlusion Only

Only use the collection to produce occlusion.

## Exclude

Don't use this collection in line art.

## Intersection only

Only generate intersection lines for this collection

## No Intersection

Include this collection but do not generate intersection lines.

## Collection Mask

Use custom intersection masks for faces in this collection.

## Masks

You can use up to 8 masks, starting with value 0.

## Intersection Priority

Assign intersection priority value for this collection.

## Priority Value

The intersection line will be included into the object with the higher intersection priority value.

## Object Tab

The Object tab contains all general object related settings like Transform, Relation or Collection related things. Cycles has two more panels.

## Object Data Prop

Displays what object is currently selected.

## Object browser

A list of the objects in the scene. In this list you can also choose another object. And you can rename the object.

## File selector menu

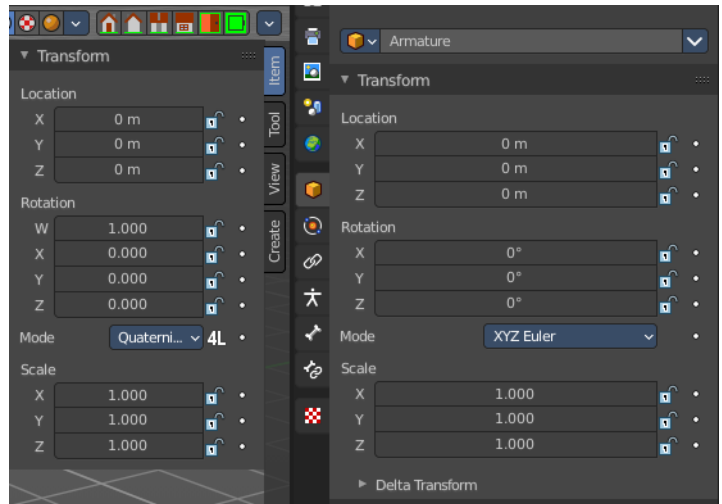

This menu has no meaning in this context. All menu items are disabled.

# Transform Panel

Transform is position, rotation and scale of the object. It is partially the same content that you see in Object mode in the Properties sidebar in the 3D view.

However, when you switch to Edit mode, with a Bone for example, then you will still have the overall world transform values for the object here, while the Transform panel in the Properties sidebar now displays the edit transform values for the bone.

## Location

The location of the object.

## Rotation

The rotation of the object.

## Rotation Mode

The rotation mode. Euler angles are fine for most needs. But sometimes you want to use Quaternion to avoid gimbal lock. Gimbal lock is a mathematical problem where the rotation locks up in two instead of three degrees of freedom.

## Quaternion

With euler angles you will have three values available. But with a quaternion you will have four values available. And quaternions reveals a 4L button. This button shows or hides a lock behind the W value. Normally a quaternion has just three locks, one for each of the single axis. The W value is a mathematical construct from the three object axis. And you usually neither want to edit it nor to lock it therefore.

Locking the W axis will lock all axis.

## Scale

The scale of the object.

## Lock

This properties can be locked.

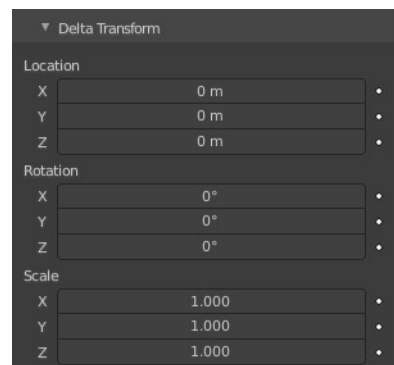

## Animate Properties

This properties can be animated. Activating the Animate Property button sets a keyframe.

### Delta Transform

Transforms are absolute to the world coordinates. Delta Transforms are relative to the current transformation.

Adjust the delta transforms.

### Delta Location

The delta location of the object.

### Delta Rotation

The delta rotation of the object.

### Delta Scale

The delta scale of the object.

## Lock

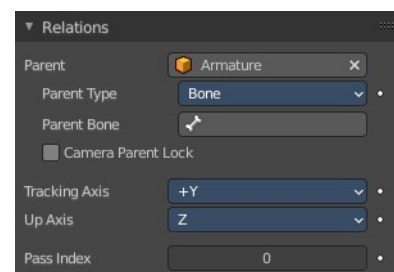

This properties can be locked.

## Animate Properties

This properties can be animated. Activating the Animate Property button sets a keyframe.

## Relations Panel

Set up and adjust relations for the object.

## Animate Properties

The properties with the Animate Property at the right can be animated. Activating the Animate Property button sets a keyframe.

## Parent

Set a parent object. One way is by the object picker at the right. Or choose the object in the list. This list

appears by clicking at the edit box.

## Parent Type

See and set the parent type.

## Parent Bone

When you parent an object to an armature then you can choose to which bone you want to parent this object.

## Camera Parent Lock

When the camera is locked to the view and in fly mode, transform the parent rather than the camera.

## Tracking Axis

The axis that points in forward direction.

## Up Axis

The axis that points in the up direction.

## Pass Index

The index number for the "Object Index" render pass.

# Collections Panel

Collections is a bunch of data, objects, cameras, lights, etc., which you can manage in some ways at once. You can for example hide complete collections, include or exclude it from rendering, instance them, and so on.

An object must be at least in one collection. Or it gets deleted. But an object can be in multiple collections. This panel allows you to manage in what collection(s) the object is.

## Link to existing collection

A drop down box where you can choose the collection that you want to add the object to. Different from the Link to collection tool in the outliner, this tool lists all collections in the Blender file. Also collections that are not to see in the Scenes or View Layer view.

## Add to new Collection

At the end of the Add to Collection element is a + button where you can create more collections.

Note that this new created collection is not part of the scene. But shows just at the Blend file level in the outliner. So when you want to create a collection that is accessible from the scene, then create the collection in the outliner instead.

Collections at the scene levels usually gets created with the name Collection + space + single Number.

Collections at the Blend file level gets created with Collection + dot + three digit number

## Collection

This is the collection where the object is currently assigned at. As told, an object can be assigned to more than one collection.

## Collection Name

Read and edit the collection name.

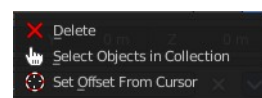

## Remove

This deletes the collection from the object. Note that the collection still exists.

## Collections Menu

### Delete

This deletes the collection from the object. Note that the collection still exists.

### Select Objects in Collection

Selects all objects in the collection.

## Set Offset From Cursor

Set offset used for collection instance based on cursor position. Normally the offset is based at the center of the world when instancing, at 0/0/0. When you choose Set Offset From Cursor then this offset is set form the cursor position instead of the world center.

## Offset

Offset from the origin to use when instancing.

# Instancing Panel

Here you find settings for instancing. Instancing means the object exists just one time in ram, and gets reused.

Instancing requires a special setup.

The duplicated geometry by this method are instances of the parent object. And so they cannot be threaten like real objects.

To turn them into editable geometry go to Object menu, and choose Apply / Make Duplicates real.

## None

No duplication happens.

## Instanceverts

InstanceVerts is the duplication of a base object at the location of the vertices of a mesh. In other words, an instance of the base object is placed on every vertex of the mesh.

### Workflow:

Create a cube, create a sphere. For demonstration purposes, move the sphere a bit off. Parent the sphere to the cube. Cube must be the parent, sphere the child.

Select just the cube. In the Duplication Panel enable Verts.

As a result you will now have eight spheres around the child sphere, since the cube has eight vertices. The center point is the sphere.

## Instanceverts Tools

### Animate Property

The properties with the Animate property at the right can be animated. You create a keyframe by clicking at it.

### Align to Vertex Normal

Orients the child objects along the normals of the parent vertices.

### Show Instancer

#### Viewport

Show the instance object in the viewport.

#### Render

Show the instance object in the final rendering.

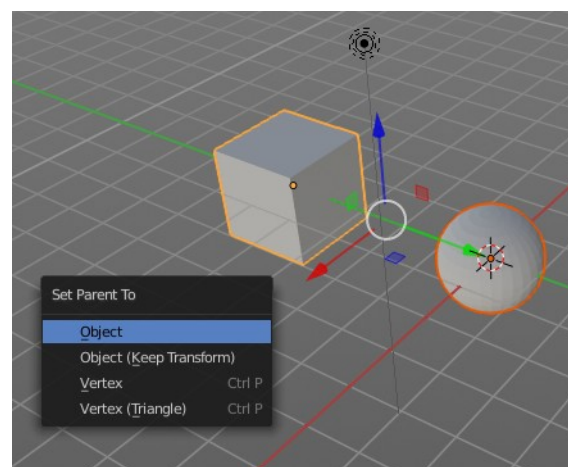

## Dupliface

DupliFaces replicates an object on each face of a parent object, using the initial child object as the center. The faces of the parent object is the pattern that gets used as the pattern to create the duplicated objects. The child object gets used as the center point, and of course to duplicate the geometry from.

### Workflow:

Create a cube, create a sphere. Move the cube a bit off. Parent the sphere to the cube ( select sphere, hold down shift, select cube, press ctrl p). Cube must be the parent, sphere the child.

In the Duplication Panel enable Faces.

As a result you will now have six spheres at the child sphere, since the cube has six sides.

### Note

*The location, orientation, and scale of the duplicated child(ren) matches that of the faces of the parent. So, if several objects are parented to the cube, they will all be duplicated once for each face on the cube. If the cube is subdivided, every child will be duplicated for each face on the cube.*

## Instance Face Tools

### Animate Property

The properties with the Animate property at the right can be animated. You create a keyframe by clicking at it.

### Show Instancer

#### Viewport

Show the instance object in the viewport.

#### Render

Show the instance object in the final rendering.

### Scale by Face Size

When you tick scale by face size then you can control the size of the child objects.

With Scale ticked you can also influence the size of the child objects by changing the parent geometry.

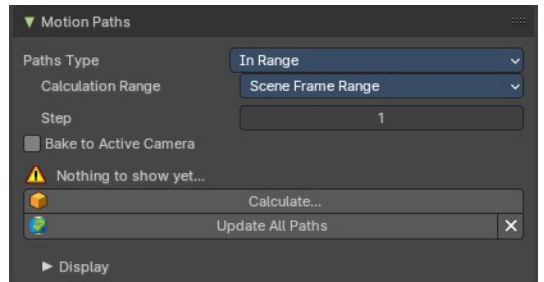

### Factor

The scale factor for scale.

# Motion Paths Panel

Motion paths is a visual helper to judge the motion of objects.

Motion paths are not displayed by default. They need to be calculated. This can be done here.

## Workflow:

We simply need a motion animation first. For example a moving cube.

Add a cube. Choose a keying set. Set a keyframe at let's say frame 0. Go to frame 20. Move the object. Set a keyframe at frame 20.

Click Calculate. You will now see the motion path of this object.

## Motion Paths Tools:

### Paths Type

There are two path types available. In Range and Around Frame.

### Around Frame

Displays just the motion path around the current frame. Not the whole path.

### Frame Range before

The frames to display before the current frame.

### After

The frames to display after the current frame.

### Step

Number of frames between paths shown.

### In Range

Displays the full motion path.

## Calculation Range

The type of path range to calculate the motion paths.

### All Keys

Calculate all keys. Even when they are out of the range.

### Step

Number of frames between paths shown.

### Selected Keys

Calculate just selected keys.

### Step

Number of frames between paths shown.

### Scene Frame Range

Calculate the entire scene / preview range.

### Step

Number of frames between paths shown.

### Manual Range

Manually determine frame range.

### Frame Range Start

The start frame.

### End

The end frame.

### Step

Number of frames between paths shown.

---

## Bake to active camera

Motion path points will be baked into the camera space of the active camera. This means that they will only look right when looking through this specific camera then. Switching cameras using markers is not supported.

## Cached range

Not editable. Internal cache information.

## Update Paths

Update the paths after any changes at the animation. You have to update the paths too if you change settings like the paths type.

## Update All Paths

Update all paths after any changes at the animation. You have to update the paths too if you change settings like the paths type.

## Delete Paths

Deletes ALL motion paths caches in the scene. Hold down shift to delete just the path for the current object.

## Display subpanel

Here you find some display options for the path.

### Frame Numbers

Display the frame number above every knot of the motion path

### Keyframes

Display the keyframes in the path as orange dots.

### Keyframe Numbers

Display the keyframe number above every keyframe.

### Lines

Display a line between the points.

### Thickness

The line thickness.

### Custom Color

Define a custom color for the motion path. You can set a Before color for everything before the current frame. And a After color for everything after the current frame. A click at the color area opens a color picker.

## Motion Blur Panel - Cycles

The Motion Bur panel gives you further per object options for motion blur.

Note that Motion Blur needs to be active to make this options work.

You can activate Motion Blur in the render settings.

## Shading - Cycles

The Shading panel gives you further per object shading options with the Cycles renderer.

Note that not all objects have all subpanels. Lights does for example just contain the Light Group sub panel.

### Shadow Terminator subpanel

#### Geometry Offset

Offset rays from the surface to minimize shadow artifacts at low poly geometry. Only affects triangles at grazing angles to light.

#### Shading Offset

Push the shadow terminator towards the light to minimize shadow artifacts at low poly geometry.

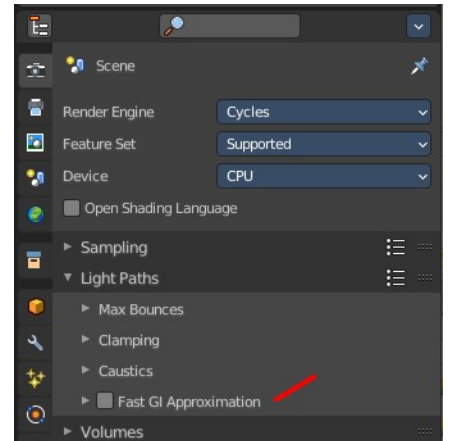

## Fast GI Approximation subpanel

### AO Distance

The Ambient Occlusion distance that is used for approximate Ambient Occlusion. 0 means the world settings are used.

Note that Fast GI Approximation needs to be active to make this options work.

## Caustics subpanel

Caustics related settings.

### Cast Shadow Caustics

Generates caustics in case the material is a refractive material. Casting lights must have shadow caustics option enabled. This can be found in the object data properties in the Light panel.

### Receive Shadow Caustics

Receive caustics in case the material is a refractive material. Casting lights must have shadow caustics option enabled. This can be found in the object data properties in the Light panel.

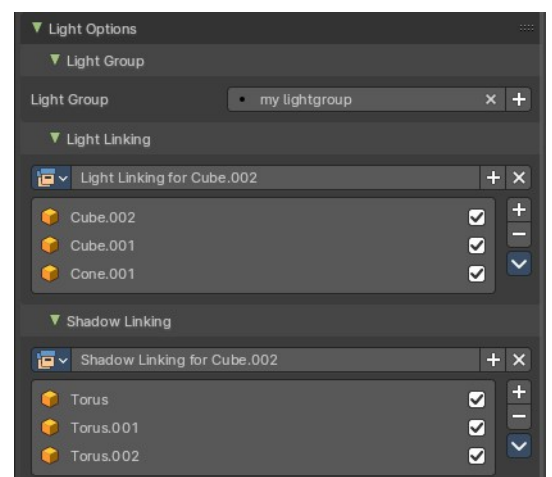

## Light Options - Cycles

Allows you to assign the current object or light source to a Light Group.

**Note:** Objects must be have an emission material to have an influence in the Light Group.

The content in the Lists can be dragged around to change the order.

The objects can be enabled and disabled by the checkbox at the

right.

## Light Group

Assign the light source or an object with an emission material to a Light Group.

You first need to create a Light Group in the View Layer Properties > Passes > Lightgroups panel. Then you can choose from the existing Light Groups. Or you simply type in the name of a new light group. Then click at the add button besides the edit box.

For more information, check out the Properties Editor - View Layer Properties chapter.

## Light Linking

Here you create and assign a Light Linking group to objects and collections. This assists in including or excluding objects from a lights influence. Default assignment of a Light Group will influence everything in the scene.

**Note:** Consider this as an exclusive override for light group influence of an emission object or light source.

## Data property

### Data Browser

Shows the available light linking collections that you can choose. This can be single objects, or whole collections.

### Name

The current active group name. The name can be renamed.

### Display number

How much users this data has. A click at it makes it a single user object.

### New Light linking collection

Add a new light linking collection.

### Remove

Removes the light linking collection as the active collection. Note that the collection will still be in the data browser.

### Collection List

The list of objects in the light linking collection.

## Link Receivers to Emitter

Light link selected receivers to the active emitter object.

## Remove from light linking collection

Removes the object not only from the light linking, but also from the scene.

## Select Light Linking Receivers

Selects the selected objects in the list in the scene too.

---

## Shadow Linking

Here you create and assign a Shadow Linking group with objects and collections. Shadow linking additionally gives control over which objects acts as a shadow blocker or shadow exception for the light sources of a Light Group.

## Data property

### *Data Browser*

Shows the available light linking collections that you can choose. This can be single objects, or whole collections.

### *Name*

The current active group name. The name can be renamed.

### *Display number*

How much users this data has. A click at it makes it a single user object.

### *New Light linking collection*

Add a new light linking collection.

### *Remove*

Removes the light linking collection as the active collection. Note that the collection will still be in the data browser.

## Collection List

The list of objects in the light linking collection.

## Link Receivers to Emitter

Light link selected receivers to the active emitter object.

## Remove from light linking collection

Removes the object not only from the light linking, but also from the scene.

## Select Light Linking Blockers

Selects the selected objects in the list in the scene too.

## Visibility Panel - Eevee and Workbench

Show or hide options for the selected object.

### Animate property

These property can be animated. Clicking at the decorator at the right sets a keyframe.

### Show In

#### Viewports

Show the object in the viewport. This can also be done in the outliner.

#### Renders

Show the object in the rendering. This can also be done in the outliner.

#### Grease Pencil

#### Use Lights

Grease Pencil object only. Light affects grease pencil object.

#### Mask

#### Holdout

Render the object as a holdout or matte object. This creates a hole in the image in the shape of the object. Which can then be filled with content in the compositing process.

## Visibility Panel - Cycles

Note that the content does not show with all object types. The content shown here is with a mesh object.

Show or hide options for the selected object.

### Animate property

These property can be animated. Clicking at the decorator at the right sets a keyframe.

## Show in

### Viewports

Show the object in viewports.

### Renderers

Show the object in renderers.

## Ray Visibility Subpanel

The object visibility for different types of rays.

## Culling

### Use Camera Cull

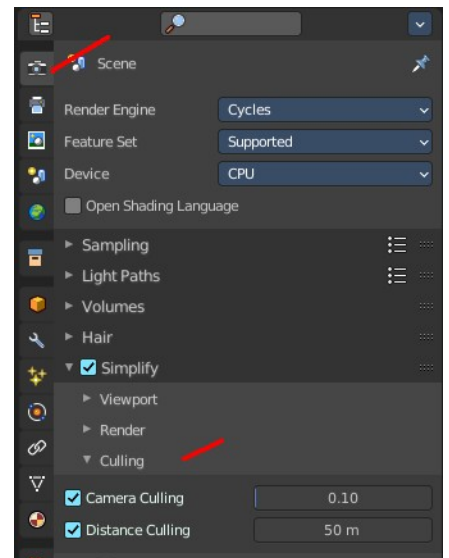

Allow objects and its duplicates to be culled by the camera space culling.

This option is just active when Simplify in the Render tab is activated, and the camera culling in the simplify panel is ticked too.

### Use Distance Cull

Allow objects and its duplicates to be culled by the specified distance.

This option is just active when Simplify in the Render tab is activated, and the camera culling in the simplify panel is ticked too.

## Line Art Panel

Line Art settings.

### Usage

How to use this object in line art calculation. The items should be self explaining.

### Override crease

Use this objects crease settings to override scene global.

## Crease

Angles smaller than this value will be treated as creases.

## Viewport Display Panel

Here you will find some further display options for the object. Object name, Wire Frame in Object Mode, etc.

Some of these settings will override general settings. For example when you set the maximum draw type (Display as) to Wire, then it will always display as wire, regardless if you set the Viewport render method to Material or Textured.

The content is different for different object types. Mesh objects have more options than a grease pencil for example.

Note also that some objects have some further special viewport settings in other tabs. For example, Bones have also viewport settings in the Object Data properties, and in the Bone properties.

This panel here is for general viewport display settings for the objects.

## Animate property

These properties can be animated. Clicking at the decorator at the right sets a keyframe.

## Show

### Name

Display the object name at the pivot point.

### Axis

Display the objects axis. Best done with Wireframe display mode. Solid faces may hide the axis. Or tick in Front. Then the axis gets also drawn above the mesh faces.

### Wireframe

Display parts of the wire frame in Object Mode. See All Edges.

## All Edges

This is a hieronymus bosch feature from Blender developers that will most probably trap you again and again. When you tick Wireframe then SOME of the edges of the object gets displayed. You need to tick all edges to display the whole Wireframe.

## Texture Space

Display the objects texture space. This has to do with the mapping. A sphere can for example have a cubic mapping.

## Shadow

The object should throw a shadow in the 3D view. But it seems to be dysfunctional.

## In Front

X Ray. Display this object in front of all other objects.

## Color

Solid mode setting only.

When you set the Color type to Object in the viewport shading settings, then the object in the viewport is displayed with this color.

## Display As

Adjust the maximum display method for the object. For example when you set the maximum draw type to Wire, then it will always display as wire, regardless if you set the Viewport render method to Material or Textured.

## Bounds

Display the bounding box for this object.

### Display Bounds Type

What shape to choose for the bounding box. There is more than just the classical box shape available.

## Custom Properties Panel

Define custom properties that can be used for scripting.

Here you might also find custom properties from addons or scripts.

## Add

Adds a new property.

## Edit

A panel to adjust the settings for the custom property.

## Remove

Removes the property.

## Color modifiers

Color modifiers just exists for the Grease Pencil object.

### Hue/Saturation

The Hue/Saturation Modifier applies a color transformation to the object output color.

### Mode

The color transformation will be applied on the stroke and/or the fill color.

Stroke and Fill, Stroke, Fill

### Hue

Specifies the hue rotation of the image. 360° are mapped to (0 to 1). The hue shifts of 0 (-180°) and 1 (+180°) have the same result.

### Saturation

A saturation of 0 removes hues from the image, resulting in a greyscale image. A shift greater than 1.0 increases saturation.

### Value

Value is the overall brightness of the image. De/Increasing values shift an image darker/lighter.

### Influence

#### Layer

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

#### Invert

Inverts the influence.

#### Pass

The layer pass index.

#### Invert

Inverts the influence.

## **Material**

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

## **Invert**

Inverts the influence.

## **Pass**

The material pass index.

## **Invert**

Inverts the influence.

## **Custom Curve**

Use a custom curve to define the noise along the strokes.

## **Navigation elements**

The navigation elements at the top are described from left to right.

## **Zoom in and out**

The two buttons with the magnifying glass at it zooms in and out in the curve window.

## **Tools**

Tools is a menu where you can find some curve related tools.

### **Reset View**

Resets the curve windows zoom.

### **Vector Handle**

Set handle type to Vector.

### **Auto Handle**

Set handle type to Auto.

### **Auto Clamped Handle**

Set handle type to Auto Clamped.

### **Extend Horizontal**

Extend the curve points horizontal before the first curve point and after the last curve point.

## Extend Vertical

Extend the curve points vertical before the first curve point and after the last curve point.

## Reset Curve

Resets the curve to the initial shape.

## Use Clipping

Clipping options. Set up clipping for the stroke.

## Delete Points

Deletes selected curve points.

## Curve window

Tweak and adjust the falloff curve by clicking at a curve point and dragging it around.

Double click adds a new point.

Holding down ctrl activates temporary snapping.

Holding down shift enables slower movement, which allows more accurate setting.

## X / Y

The position of the currently selected curve point.

## Opacity Modifier

The Opacity Modifier change the opacity (alpha) value of the stroke points.

The alpha value in Grease Pencil is stored per-point. The modifier can alter these values to go from totally transparent points to totally opaque points.

## Mode

The color transformation will be applied to the stroke/fill color or stroke Hardness. When Hardness is selected, then the opacity affects the stroke's transparency (alpha) from the center to the border.

Stroke and Fill, Stroke, Fill, or Hardness.

## Uniform Opacity

When enabled, makes the opacity equal for the entire strokes.

## Opacity Factor

Controls the opacity value of the stroke points. A value of 1.0 respect the original alpha value of the points, a shift less than 1.0 make the points more transparent than originally, and a shift greater than 1.0 make the points more opaque than originally.

Sets value to 2.0 makes the points alpha fully opaque.

## Weighted

Use Weight to modulate effect.

## Influence

### Layer

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### Invert

Inverts the influence.

### Pass

The layer pass index.

### Invert

Inverts the influence.

### Material

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

### Invert

Inverts the influence.

### Pass

The material pass index.

### Invert

Inverts the influence.

### Vertex Group

Limit the influence to a vertex group.

### Invert

Inverts the influence.

## Custom Curve

Use a custom curve to define the noise along the strokes.

### Navigation elements

The navigation elements at the top are described from left to right.

### Zoom in and out

The two buttons with the magnifying glass at it zooms in and out in the curve window.

## Tools

Tools is a menu where you can find some curve related tools.

### Reset View

Resets the curve windows zoom.

### Vector Handle

Set handle type to Vector.

### Auto Handle

Set handle type to Auto.

### Auto Clamped Handle

Set handle type to Auto Clamped.

### Extend Horizontal

Extend the curve points horizontal before the first curve point and after the last curve point.

### Extend Vertical

Extend the curve points vertical before the first curve point and after the last curve point.

### Reset Curve

Resets the curve to the initial shape.

## Use Clipping

Clipping options. Set up clipping for the stroke.

### Delete Points

Deletes selected curve points.

## Curve window

Tweak and adjust the falloff curve by clicking at a curve point and dragging it around.

Double click adds a new point.

Holding down ctrl activates temporary snapping.

Holding down shift enables slower movement, which allows more accurate setting.

## X / Y

The position of the currently selected curve point.

## Tint Modifier

The Tint Modifier colorize the original stroke or fill with a selected color.

## Mode

The color transformation will be applied on the stroke and/or the fill color.

Stroke and Fill, Stroke, Fill

## Strength

Controls the amount for the color mixing.

A value of 0 respect the original strokes vertex color, a value of 1.0 totally replace the original color with the tint color.

A shift greater than 1.0 will make the points alpha less transparent than originally (2.0 is fully opaque).

## Weighted

Use weight to modulate effect.

## Tint Type

### Uniform

#### Color

Defines the tint color for mixing with the original color.

## Gradient

### Color Ramp

Defines the tint gradient color for mixing with the original vertex color.

### Controls

+

Add a stop to your color ramp. The stop will be added after the selected one, in the middle to the next one.

-

Deletes the selected color stop from the list.

### Tools menu

#### Flip Color Ramp

Flips the gradient, inverting the values of the color ramp.

#### Distribute Stops from Left

Rearrange the stops so that every step has the same space to the right.

#### Distribute Stops Evenly

Space between all neighboring stops becomes equal.

#### Eyedropper (pipette icon) E

An Eyedropper to sample a color or gradient from the interface to be used in the color ramp.

#### Reset Color Ramp

Resets the color ramp to its default state.

### Color Mode

#### RGB

Blends color by mixing each color channel and combining.

#### HSV/HSL

Blends colors by first converting to HSV or HSL, mixing, then combining again. This has the advantage of maintaining saturation between different hues, where RGB would de-saturate, this allows for a richer gradient.

### Interpolation

#### Ease

Uses an Ease Interpolation for the color stops.

#### Cardinal

Uses a Cardinal Interpolation for the color stops.

#### Linear

Uses a Linear Interpolation for the color stops.

#### B-Spline

Uses a B-Spline Interpolation for the color stops.

## Constant

Uses a Constant Interpolation for the color stops.

## Color Ramp

The color band. A click at one of the color stops makes it the active one. You can move the color stops by clicking at them and dragging them around.

## Active Color Stop elements

Adjust the active color stop.

## Choose active color stop

Choose the color stop by index.

## Pos

The position of the active color stop. The range goes from 0.000 to 1.000.

## Object

A Data ID to select an object (usually an empty), which position and rotation will be used to define the center of the effect.

## Radius

Defines the maximum distance of the effect.

## Influence

### Layer

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### Invert

Inverts the influence.

### Pass

The layer pass index.

### Invert

Inverts the influence.

### Material

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

### Invert

Inverts the influence.

## **Pass**

The material pass index.

## **Invert**

Inverts the influence.

## **Vertex Group**

Limit the influence to a vertex group.

## **Invert**

Inverts the influence.

## **Custom Curve**

Use a custom curve to define the noise along the strokes.

## **Navigation elements**

The navigation elements at the top are described from left to right.

## **Zoom in and out**

The two buttons with the magnifying glass at it zooms in and out in the curve window.

---

## **Tools**

Tools is a menu where you can find some curve related tools.

### **Reset View**

Resets the curve windows zoom.

### **Vector Handle**

Set handle type to Vector.

### **Auto Handle**

Set handle type to Auto.

### **Auto Clamped Handle**

Set handle type to Auto Clamped.

### **Extend Horizontal**

Extend the curve points horizontal before the first curve point and after the last curve point.

### **Extend Vertical**

Extend the curve points vertical before the first curve point and after the last curve point.

### **Reset Curve**

Resets the curve to the initial shape.

---

### **Use Clipping**

Clipping options. Set up clipping for the stroke.

### **Delete Points**

Deletes selected curve points.

---

### **Curve window**

Tweak and adjust the falloff curve by clicking at a curve point and dragging it around.

Double click adds a new point.

Holding down ctrl activates temporary snapping.

Holding down shift enables slower movement, which allows more accurate setting.

### **X / Y**

The position of the currently selected curve point.

## 26.9.1 Editors - Properties Editor - Modifiers Properties Tab - Add Modifier menus

Unassigned (Catalogue).....	5

### Add Modifier menu buttons

There are two types of modifiers, builtin modifiers and geometry nodes modifiers that were marked as assets.

#### Add Modifier Button

The button to the left adds built in modifiers to all selected objects.

*Note: When adding modifier assets will apply to all selected object.*

#### Add Asset Modifier

The button to the right adds geometry nodes assets as modifiers to all selected objects.

*Note: When adding modifier assets will apply to all selected object.*

## Add Modifier menu

This menu with a list of modifier items adds built in modifiers to all selected objects. This shows with all objects.

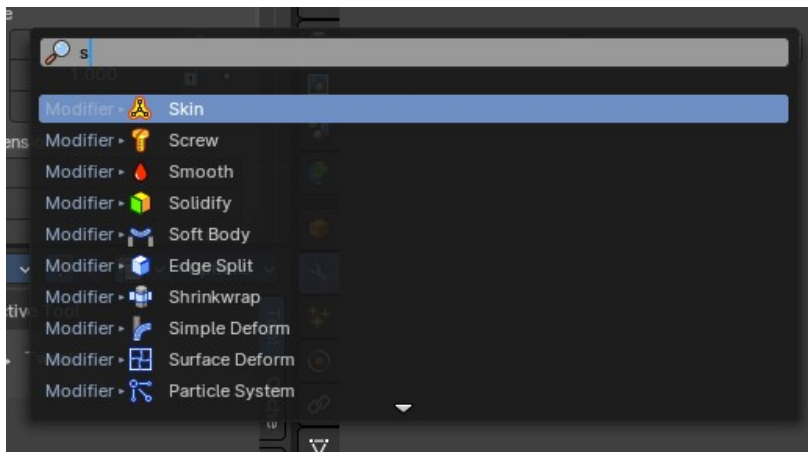

These are divided into four categories:

- Normals
- Edit
- Generate
- Deform
- Physics

Select any entry to add the modifier.

## Type to Search...

When the menu is open, you can press any key to start typing to search, this will filter the modifiers by name.

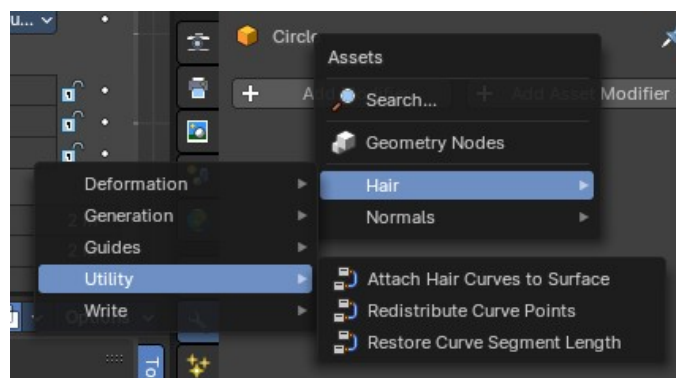

## Add Asset Modifier menu

There is also an add asset modifier menu items that shows all Geometry Node groups marked as assets that you can add as a modifier to all selected objects.

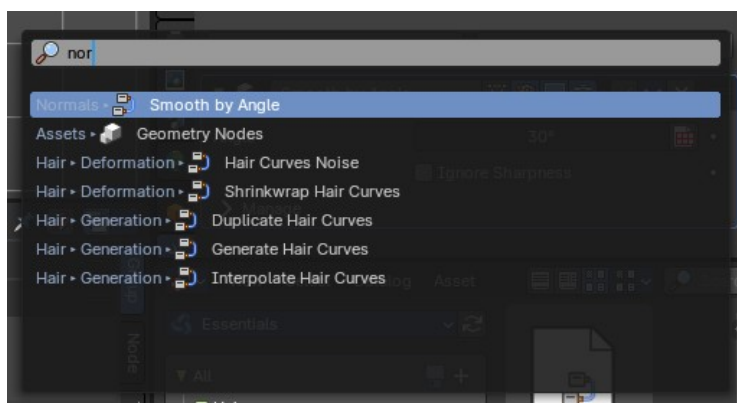

## Search...

Search for a specific modifier.

## Type to Search...

When the menu is open, you can press any key to start typing to search, this will filter the asset modifiers by name.

## Geometry Nodes

Add a geometry nodes modifier.

This is usually done in the Geometry Nodes Editor.

The geometry Nodes modifier adds a geometry node tree, which can be modified in the geometry node editor.

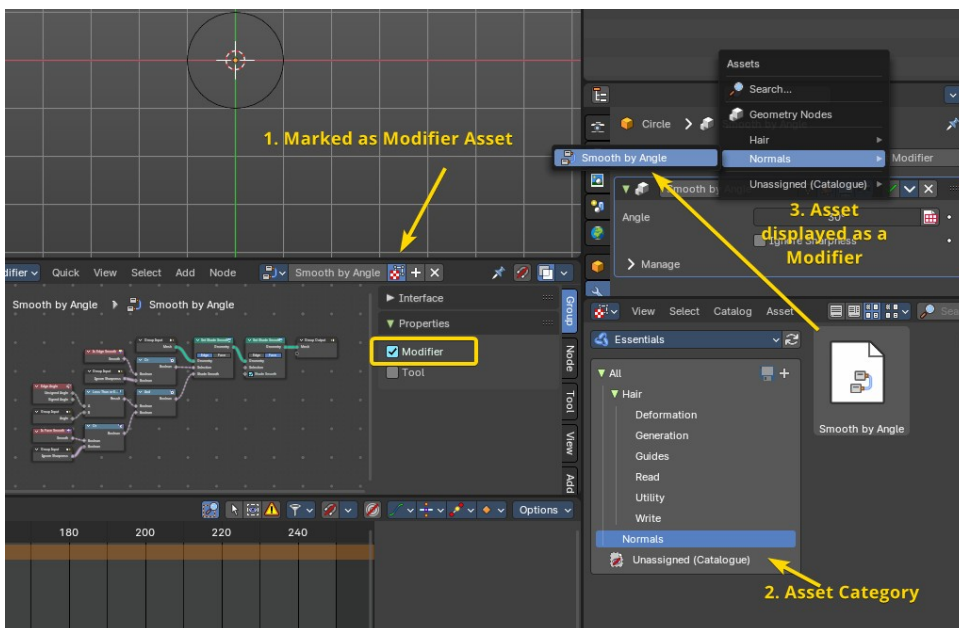

Manage the nodes. If there is no geometry node tree for the current object, then you will see the New button.

## Geometry Nodes Assets

These are Geometry Node groups that have been marked as assets, set as a “Modifier” in the node group properties, and organized into an Asset Browser category.

1 . Mark Node Group as asset and set the Node Group properties to “Modifier”, so this will show in the Modifier stack. Do this from the Geometry Nodes editor.

2. Assign the Nodegroup to a category in the File Browser Editor.

3.

Now you can use the Add Asset Modifier menu to quickly assign a new Geometry Nodes Asset Modifier preset to any object.

## Data Browser

The list of available geometry node trees in the scene.

## **Edit box**

The name of the current active geometry node tree. Here you can also rename the node tree.

## **Add Fake User**

With this button you assign a fake user to this selected geometry node tree.

Data, like node trees, that is not longer linked to anything else gets removed when you save and reload a scene. Bforartists has the concept of fake users to go around this behavior. An image with a fake user is in fact linked to something. And so it is not lost when you save and reload the scene.

## **User**

The number of users that uses this data. Data with a user number of 0 will be removed with closing Bforartists.

## **Add**

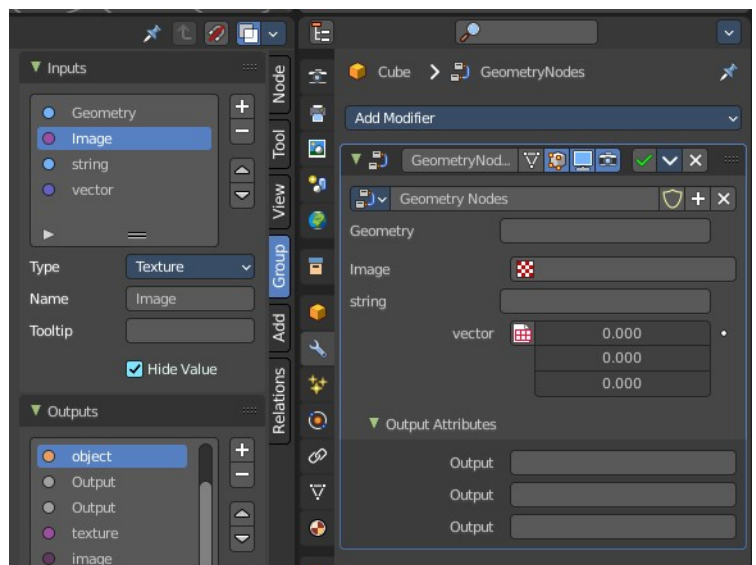

Adds a duplicate geometry nodes nodegroup.

## **Remove**

Removes the geometry node tree. To delete it completely you need to purge it. See Fake user.

## **Custom Inputs and Outputs**

In case you define custom inputs and outputs in the geometry nodes editor, then these inputs and outputs also shows in the modifier.

## **Unassigned (Catalogue)**

Custom modifier assets. This menu item shows when you for example add a geometry node, and apply it. Then this applied node tree goes into this menu which allows you to reuse it. The term non-assets is a label, and no custom asset.

## Edit modifiers

### Available content

#### Mesh object

- Normal Edit
- Weighted Normal
- Smooth by Angle Modifier Asset

### Normal Edit

The Normal Edit modifier affects (or generates) custom normals. It uses a few simple parametric methods to compute them, and mixes back those generated normals with existing ones.

Note! This modifier requires custom normals to be enabled, which can be done by enabling Auto Smooth in the Properties.

Tip. More complex normal manipulations can be achieved by copying normals from one mesh to another, see the Data Transfer Modifier. Some shading effects can also make use of the Weighted Normals modifier.

#### Mode

##### **Radial**

Aligns normals with the (origin, vertex\_coordinates) vector, in other words all normals seems to radiate from the given center point, as if they were emitted from an ellipsoid surface.

##### **Directional**

Makes all normals point (converge) towards a given target object.

#### Target

Uses this object's origin as reference point when generating normals. A Target object is optional in Radial mode, but mandatory in Directional mode.

#### Parallel Normals

Only relevant in Directional mode. Makes all normals parallel to the line between both objects' origins, instead

of converging towards target's origin.

## Mix

### Mix Mode

How to affect existing normals with newly generated ones.

Note that the Multiply option is not a cross product, but a mere component-by-component multiplication.

### Mix Factor

How much of the generated normals get mixed into existing ones.

### Vertex Group

Allows per-item fine control of the mix factor. The vertex group influence can be reverted by using the small “arrow” button to the right.

### Max Angle

Forbids new generated normals to have an angle to the original normal above that given threshold. This is useful to prevent extreme changes, that can even lead to inverting the front/back sides of a face, and consequently to ugly shading artifacts.

### Lock Polygon Normals

Prevents flipping (reversing front/back sides) of polygons which normal does not match anymore the side to which point its corners' custom normals. Can also help avoiding shading issues.

## Offset

Gives the origin of the modified object an offset before using it to generate normals.

Offset is only relevant in Radial mode if no Target Object is set, and in Directional mode when Parallel Normals is set.

## Weighted Normal

This modifier allows you to change the custom normals of a mesh. This can be useful to make some faces appear very flat during shading, among other effects.

## Weighting Mode

The normals around a vertex will be combined to create a custom (per face corner) normal using various weights for each. The Weighting Mode defines how to compute the weights.

### **Face Area**

Weight according to the area of the face that the normal originates. A larger area means that the normal from that face will get a higher weight in final result.

### **Corner Angle**

Weight according to the angle each face forms at the vertex.

### **Face Area and Angle**

Weights are obtained by multiplying the face area and corner angle ones.

## Weight

Determines how strongly the weights are biased according to the face areas and/or corner angles, a bit like a contrast setting for a picture.

A value of 50 means all faces are weighted uniformly.

More than 50 means faces with higher area or angles are given even more weight (more “contrast”).

Less than 50 means faces with higher area or angles are given lesser weights (less “contrast”).

## Threshold

A weight-rounding threshold which means that, if two angles or areas differ by less than that threshold, they will get equal weights.

## Keep Sharp

Preserve sharp edges, though smoothing will still happen if there are multiple faces between any two sharp edges.

## Face Influence

Use face weights as assigned by the Set Strength tool or by the Set Strength mode of a Bevel modifier.

For example, if three faces meet at a vertex and have the face weights weak, medium, and strong, then only the normal associated with the strong face will be used to set the final result.

## Vertex Group

If a vertex group is specified, the modifier will only affect those vertices.

### ***Invert***

Invert the selection (only affect the vertices not in the vertex group).

---

## Smooth by Angle Modifier Asset

This modifier asset is a Geometry Nodegroup that does an “autosmooth” operation on the normals. By default this will consider edges that have been marked as sharp.

### **Angle**

The autosmooth angle the smoothing will happen. Any face normal that is less than this amount will contain smooth normal angles.

### ***Input Attribute Toggle***

This can also be toggled to set by an attribute set by Geometry Nodes.

### **Ignore Sharpness**

This will override the edges that have been marked sharp and smooth the neighboring face normals accordingly.

### **Manage**

Advanced Geometry Nodegroup options.

### ***Bake***

Bake the information to a cache on disk.

### **Bake Path**

The custom path this particular modifier asset will store the frames. You can define the path where these will bake per Geometry Nodes modifier. If not defined, it will default to the \*.blend file location. To bake, you must save the file first.

### ***Named Attributes***

No named attributes are used with this modifier asset.

## Edit modifiers

### Available content

#### Mesh object

- Data Transfer
- Mesh Cache
- Mesh Sequencer Cache
- UV Project
- UV Warp
- Vertex Weight Edit
- Vertex Weight Mix
- Vertex Weight Proximity

#### Curve + Text object

- Mesh Cache
- Mesh Sequencer Cache

#### Lattice Object

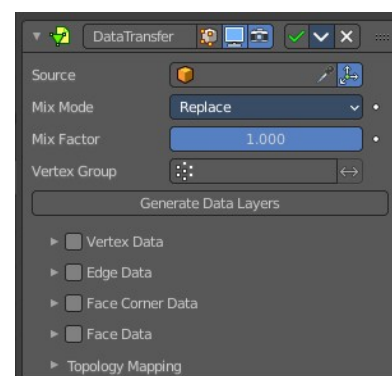

- Mesh Cache

### Data Transfer

The Data Transfer modifier transfers several types of data from one mesh to another. Data types include vertex groups, UV maps, vertex colors, custom normals...

Transfer works by generating a mapping between source mesh's items (vertices, edges, etc.) and destination ones, either on a one-to-one basis, or mapping several source items to a single destination one, using interpolation.

### Usage

Using this modifier will not create destination data layers. Use the Generate Data Layers button for this purpose when you are done with selecting the set of source data to transfer.

Creating those data layers on destination mesh is not part of the modifier stack. This means that they will remain. Even once the modifier is deleted, or if the source data selection is modified.

### Source Object

Mesh object to copy the data from.

## Object transform

Evaluate the source and destination objects in global space instead of local space.

## Mix Mode

How to mix the destination elements with the source elements.

## Mix Factor

How much of the transferred data gets mixed into existing one (not supported by all data types).

## Vertex Group

Allows per-item fine control of the mix factor. Vertex group influence can be reverted using the small “arrow” button to the right.

## Generate Data Layers

This modifier cannot generate needed data layers itself. Adjust the settings to your needs, then press this button to generate matching destination layers, if needed.

## Vertex data

Activate this group when you want to transfer vertex data.

### Vertex Groups / Bevel Weight

Which vertex data layers to transfer. Vertex groups or Bevel weight.

### Mapping

The vertex mapping method to use.

### Vertex Groups

Just active with data layer Vertex groups.

### Layer Selection

What layer from the source object gets selected.

### Layer Mapping

How to match the destination layer.

## Edge Data

Activate this group when you want to transfer edge data.

## ***Sharp, UV Seam, etc.***

Which edge data layers to transfer. You can just use one method.

### ***Mapping***

The edge mapping method to use.

## **Face Corner Data**

### ***Custom normals, Vertex Colors, UV's***

Which face corner data to transfer. You can just use one method.

### ***Mapping***

The face corner data mapping method to use.

### ***Vertex Colors***

Further settings for when you choose Vertex colors.

#### **Layer Selection**

Source Layer Selection.

#### **Layer Mapping**

Destination layer mapping.

### ***UV's***

Further settings for when you choose UV's.

#### **Layer Selection**

Source Layer Selection.

#### **Layer Mapping**

Destination layer mapping.

### **Island Precision**

The factor to control the island handling. A value of 0.0 means no island handling. A value of 0.02 is a good starting point.

## Face Data

### Smooth / Freestyle Mark

Which poly data layers to transfer.

### Mapping

The face mapping method.

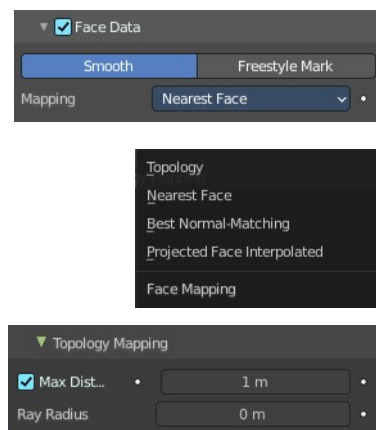

### Topology Mapping

#### Max Distance

Only Neighbor Geometry. For non topology mapping, the source elements must be closer than the value in the edit box.

#### Ray Radius

The width of rays.

## Mesh Cache

The Mesh Cache modifier allows you to apply animated mesh data to a mesh. And deform it when playing back.

This works in a similar way to shape keys. But uses external files, and allows to interchange between applications.

Tip! Both MDD and PC2 depend on the vertex order on the mesh remaining unchanged. This is a limitation of this method, so take care not to add/remove/reorder vertices once this modifier is used.

### Format

The input file format (currently .mdd and .pc2 are supported).

### File Path

Path to the cache file.

### Influence

Factor to adjust the influence of the modifier's deformation.

### Deform Mode

This setting defaults to Overwrite which will replace the vertex locations with those in the cache file.

When you want to mix a mesh cache file with shape keys, then you can select the Deform option which integrates deformations with the mesh cache result.

Note that this feature is limited to making smaller, isolated edits and will not work for larger changes such as

re-posing limbs.

## Interpolation

The blend mode between frames. Use linear when the frames in the cache file do not match up exactly with the frames in the blend-file.

## Vertex Group

Which vertex group determines the influence of the modifier per point.

## Time Remapping

### *Frame / Time / Factor*

How time is calculated.

### *Play Mode*

How playback operates.

### *Frame Start*

Play the cache starting from this frame.

### *Frame Scale*

Scale time by this factor (applied after the start value).

## Axis Mapping

### *Forward/Up Axis*

The axis for forward and up used in the source file.

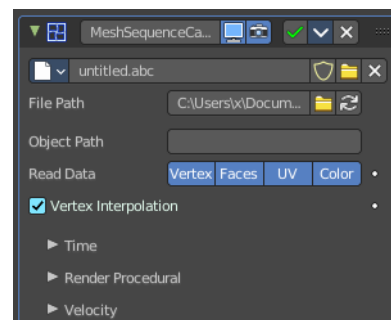

### *Flip Axis*

Allows you to flip the coordinates on an axis.

## Mesh Sequence Cache

The Mesh Sequence Cache modifier loads data from Alembic files. It supports static meshes, but is mostly used to load animated meshes. Despite its name, this modifier also supports curves. It also handles file sequences, as well as meshes and curves with varying topology (like the result of fluid simulations).

When importing an Alembic file, Mesh Sequence Cache modifiers are automatically added to time-varying

meshes. For time-varying object transforms (so animation of rotation, location, or scale), the Transform Cache Constraint is used.

## Data property

### **Data browser**

List of available Alembic files.

### **Name**

The name of the current active alembic file.

### **Fake User**

Keep this file in the scene even when it has no user anymore.

### **Open Cache File**

Open an alembic file.

### **Remove**

Remove the alembic file.

### **File Path**

Path to the Alembic file.

### **Load File**

Open an alembic file.

### **Refresh Active**

Update the files and paths.

### **Object Path**

Path to the object in the alembic file used to lookup geometric data.

### **Read Data**

Type of data to read for a mesh object. Vertices, polygons, UV maps and Vertex Color layers.

### **Vertex Interpolation**

Allow interpolation of vertex positions.

---

## Time Subpanel

## Sequence

Whether or not the cache is separated in a series of files.

## Override Frame

Whether to use a custom frame for looking up data in the cache file, instead of using the current scene frame.

## Frame

The time to use for looking up the data in the cache file, or to determine which to use in a file sequence.

## Frame Offset

Define a frame offset to the current frame.

---

## Render Procedural subpanel

### *Use Render Engine Procedural*

This feature is just available for Cycles, and just in an experimental state.

Display boxes as placeholders in the viewport.

### *Use Prefetch*

This feature is just available for Cycles, and just in an experimental state.

When enabled, the Cycles procedural will preload animation data for faster update.

### *Prefetch Cache Size*

This feature is just available for Cycles, and just in an experimental state.

Memory usage limit for the cache. If the data size does not fit the renderer is aborted. 0 disables the feature.

---

## Velocity subpanel

### *Velocity Attribute*

Name of the Alembic Attribute used for generating motion blur data.

### *Velocity Unit*

Define if velocity vectors are interpreted in Frame or Second.

### *Velocity Scale*

Multiplier used to control the magnitude of the velocity for time effects.

## UV Project

The UV Project modifier acts like a slide projector. It emits a UV map from the negative Z axis of a controller object (such as an empty object), and applies it to the object as the “light” hits it.

UV Project is great for making spotlights more diverse, and also for creating decals to break up repetition.

Usually, an Image Texture node mapped to the UV map that the modifier targets is added to the object’s material.

## UV Map

Which UV map to modify. Defaults to the active rendering layer.

## Aspect X/Y and Scale X/Y

Aspect and scale manipulation of the image. Only apply when a camera is used as projector object.

## Projectors

Up to ten projector objects are supported. Each face will choose the closest and aligned projector with its surface normal. Projections emit from the negative Z axis (i.e. straight down a camera or light). If the projector is a camera, the projection will adhere to its perspective/orthographic setting.

## Objects

Specify the projector object(s).

## UV Warp

The UV Warp modifier transforms an object’s UV map based on values or two objects. Its purpose is to give you direct control over the object’s UV’s in the 3D Viewport, allowing you to directly move, rotate, and scale existing UV coordinates using defined values or a controller object or bone.

## Usage

How the UV’s are warped is determined by the difference between the transforms (location, rotation and scale) of the from and to objects.

If the to object has the same transforms as the from object, the UV’s will not be changed.

Assuming the UV Axis of the modifier is X/Y and the scale of the objects is (1, 1, 1), if the to object is one unit away from the from object on the X axis, the UV’s will be transformed on the U axis (horizontally) by one full UV space (the entire width of the image).

## UV Layer

Which UV map to modify. Defaults to the active rendering layer.

## UV Center

The center point of the UV map to use when applying scale or rotation. With (0, 0) at the bottom left and (1, 1) at the top right.

## Axis U / V

The axes to use when mapping the 3D coordinates into 2D.

## Object From, To

The two objects used to define the transformation.

## Vertex Group

The vertex group can be used to scale the influence of the transformation per vertex.

## Invert

Invert the selection (only affect the vertices not in the vertex group).

## Transform

### Offset

2D Offset for the warp.

### Scale

2D Scale for the warp.

### Rotation

2D Rotation for the warp.

## Vertex Weight Edit

This modifier is intended to edit the weights of a vertex group.

The general process is the following, for each vertex:

(Optional) It does the mapping, either through one of the predefined functions, or a custom mapping curve.

It applies the influence factor, and optionally the vertex group or texture mask (0.0 means original weight, 1.0 means fully mapped weight).

It applies back the weight to the vertex, and/or it might optionally remove the vertex from the group if its

weight is below a given threshold, or add it if it is above a given threshold.

Important! This modifier does implicit clamping of weight values in the standard (0.0 to 1.0) range. All values below 0.0 will be set to 0.0, and all values above 1.0 will be set to 1.0.

Note! You can view the modified weights in Weight Paint Mode. This also implies that you will have to disable the Vertex Weight Edit modifier if you want to see the original weights of the vertex group you are editing.

## Vertex Group

The vertex group to affect.

## Default Weight

The default weight to assign to all vertices not in the given vertex group.

## Group Add

Adds vertices with a final weight over Add Threshold to the vertex group.

## Threshold

The add threshold.

## Group Remove

Removes vertices with a final weight below Remove Threshold from the vertex group.

## Threshold

The remove threshold.

## Normalize Weights

Normalize the resulting weights. Without normalizing the values are clamped between 0 and 1.

---

## Falloff subpanel

### Type

How weights are mapped to their new values.

#### Linear

No mapping.

#### Custom Curve

Allows the user to manually define the mapping using a curve.

#### Sharp, Smooth, Root and Sphere

These are classical mapping functions, from spikiest to roundest.

## Random

Uses a random value for each vertex.

## Median Step

Creates binary weights (0.0 or 1.0), with 0.5 as cutting value.

## Invert

Inverts the falloff.

## Influence

### Global Influence

The overall influence of the modifier (0.0 will leave the vertex group's weights untouched, 1.0 is standard influence).

Important! Influence only affects weights, adding/removing of vertices to/from vertex group is not prevented by setting this value to 0.0. In addition, a per-vertex fine control of the effect is possible using either a vertex group or a texture (both are mutually exclusive). The per-vertex values from those will be multiplied with the Global Influence.

### Mask Vertex Group

Choose a vertex group for masking.

## Invert

Invert vertex group mask influence.

### Mask Texture

Choose a texture for masking. Note that using a mask texture will remove the mask vertex group.

## Texture Property

### Texture Browser

A list of the available textures in the scene.

### Name

The name of the currently active texture. You can rename the texture here by clicking at the edit box.

### Fake User

Keep this texture in the scene even if it has no user.

### New Texture

Add a new texture.

### Remove

Remove the texture.

## Show Texture in Texture Tab

Jumps to the texture tab where you can edit your texture.

## Channel

Which channel of the texture to use for masking.

## Texture Coordinates

Which texture coordinates of the texture to use for masking.

## Vertex Weight Mix

Vertex Weight Mix Modifier

This modifier mixes a second vertex group (or a simple value) into the affected vertex group, using different operations.

Important! This modifier does implicit clamping of weight values in the standard (0.0 to 1.0) range. All values below 0.0 will be set to 0.0, and all values above 1.0 will be set to 1.0.

Note! You can view the modified weights in Weight Paint Mode. This also implies that you will have to disable the Vertex Weight Mix modifier if you want to see the original weights of the vertex group you are editing.

## Vertex Group A

The vertex group to affect.

## Vertex Group B

The second vertex group to mix into the affected one. Leave it empty if you only want to mix in a simple value.

## Default Weight A

The default weight to assign to all vertices not in the given vertex group.

## Default Weight B

The default weight to assign to all vertices not in the given second vertex group.

## Vertex Set

Which vertices should be affected.

Important! When using All vertices, Vertices from group B or Vertices from one group, vertices might be added to the affected vertex group.

## **All**

Affects all vertices, disregarding the vertex groups content.

## **Vgroup A**

Affects only vertices belonging to the affected vertex group.

## **Vgroup B**

Affects only vertices belonging to the second vertex group.

## **Vgroup A or B**

Affects only vertices belonging to at least one of the vertex groups.

## **Vgroup and B**

Affects only vertices belonging to both vertex groups.

## **Mix Mode**

How the vertex group weights are affected by the other vertex group's weights.

## **Replace weights**

Replaces affected weights with the second group's weights.

## **Add to weights**

Adds the values of Group B to Group A.

## **Subtract from weights**

Subtracts the values of Group B from Group A.

## **Multiply weights**

Multiplies the values of Group B with Group A.

## **Divide weights**

Divides the values of Group A by Group B.

## **Difference**

Subtracts the smaller of the two values from the larger.

## **Average**

Adds the values together, then divides by 2.

## **Influence**

### **Global Influence**

The overall influence of the modifier (0.0 will leave the vertex group's weights

untouched, 1.0 is standard influence).

Important! Influence only affects weights, adding/removing of vertices to/from vertex group is not prevented by setting this value to 0.0. In addition, a per-vertex fine control of the effect is possible using either a vertex group or a texture (both are mutually exclusive). The per-vertex values from those will be multiplied with the Global Influence.

### **Mask Vertex Group**

Choose a vertex group for masking.

### **Invert**

Invert vertex group mask influence.

### **Mask Texture**

Choose a texture for masking. Note that using a mask texture will remove the mask vertex group.

### **Texture Property**

#### **Texture Browser**

A list of the available textures in the scene.

### **Name**

The name of the currently active texture. You can rename the texture here by clicking at the edit box.

### **Fake User**

Keep this texture in the scene even if it has no user.

### **New Texture**

Add a new texture.

### **Remove**

Remove the texture.

### **Show Texture in Texture Tab**

Jumps to the texture tab where you can edit your texture.

### **Channel**

Which channel of the texture to use for masking.

### **Texture Coordinates**

Which texture coordinates of the texture to use for masking.

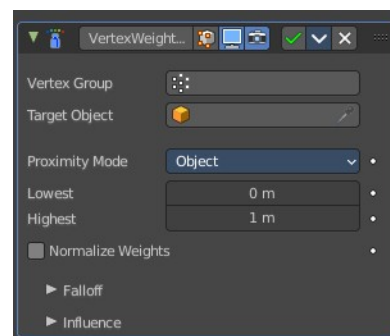

## Vertex Weight Proximity

This modifier sets the weights of the given vertex group, based on the distance between the object (or its vertices), and another target object (or its geometry).

**Warning**1 This modifier does implicit clamping of weight values in the standard (0.0 to 1.0) range. All values below 0.0 will be set to 0.0, and all values above 1.0 will be set to 1.0.

**Note!** You can view the modified weights in Weight Paint Mode. This also implies that you will have to disable the Vertex Weight Proximity modifier if you want to see the original weights of the vertex group you are editing.

### Vertex Group

The vertex group to affect.

### Target Object

The object from which to compute distances.

### Proximity mode

#### *Object*

Use the distance between the modified mesh object and the target object as weight for all vertices in the affected vertex group.

#### *Geometry*

Use the distance between each vertex and the target object, or its geometry.

**Note!** If you enable more than one of them, the shortest distance will be used. If the target object has no geometry (e.g. an empty or camera), it will use the location of the object itself.

#### **Lowest**

Distance mapping to 0.0 weight. Tip! Lowest can be set above Highest to reverse the mapping.

#### **Highest**

Distance mapping to 1.0 weight.

### Normalize Weights

Normalize the resulting weights. Without this option they get only clamped within the 0.0 - 1.0 range.

## Falloff

### Type

How weights are mapped to their new values.

### Linear

No mapping.

### Custom Curve

Allows the user to manually define the mapping using a curve.

### Sharp, Smooth, Root and Sphere

These are classical mapping functions, from spikiest to roundest.

### Random

Uses a random value for each vertex.

### Median Step

Creates binary weights (0.0 or 1.0), with 0.5 as cutting value.

### Invert

Inverts the falloff.

## Influence

### Global Influence

The overall influence of the modifier (0.0 will leave the vertex group's weights untouched, 1.0 is standard influence).

Important! Influence only affects weights, adding/removing of vertices to/from vertex group is not prevented by setting this value to 0.0. In addition, a per-vertex fine control of the effect is possible using either a vertex group or a texture (both are mutually exclusive). The per-vertex values from those will be multiplied with the Global Influence.

### Mask Vertex Group

Choose a vertex group for masking.

### Invert

Invert vertex group mask influence.

### Mask Texture

Choose a texture for masking. Note that using a mask texture will remove the mask vertex group.

## Texture Property

### **Texture Browser**

A list of the available textures in the scene.

### **Name**

The name of the currently active texture. You can rename the texture here by clicking at the edit box.

### **Fake User**

Keep this texture in the scene even if it has no user.

### **New Texture**

Add a new texture.

### **Remove**

Remove the texture.

### **Show Texture in Texture Tab**

Jumps to the texture tab where you can edit your texture.

### **Channel**

Which channel of the texture to use for masking.

### **Texture Coordinates**

Which texture coordinates of the texture to use for masking.

## Volume object

- Geometry Nodes
- Mesh to Volume

## Array

The Array modifier creates an array of copies of the base object. Each copy can offset from the previous one in any of a number of possible ways. Vertices in adjacent copies can be merged if they are nearby, allowing smooth Subdivision Surface frameworks to be generated.

This modifier can be useful when combined with tillable meshes for quickly developing large scenes. It is also useful for creating complex repetitive shapes.

Multiple Array modifiers may be active for an object at the same time. This allows to create complex three-dimensional constructs.

Hint for Offset Calculation. The transformation applied from one copy to the next is calculated as the sum of the three different components (Relative, Constant and Object), each of which can be enabled/disabled independently of the others. This allows, for example, a relative offset of (1.0, 0.0, 0.0) and a constant offset of (0.1, 0.0, 0.0), giving an array of objects neatly spaced along the X axis with a constant 0.1 unit between them, whatever the original object's size.

## Fit Type

Controls how the length of the array is determined.

### **Fixed Count**

Generates the number of copies specified in Count.

### **Fit Length**

Generates copies to fit within the fixed length given by Length.

### **Fit Curve**

Generates copies to fit within the length of the curve object specified in Curve. You need to select a curve object.

Note! Both Fit Curve and Fit Length use the local coordinate system size of the base object, which means that scaling the base object in Object Mode will not change the number of copies generated by the modifier.

Fit Length uses the local coordinate system length of the curve, which means that scaling the curve in Object Mode will not change the number of copies generated by the modifier.

Applying the scale can be useful for both.

## Relative Offset

### ***Factor X/Y/Z***

Adds a translation equal to the object's bounding box size along each axis to the offset, multiplied by a scaling factor. X, Y and Z scaling factors can be specified.

## Constant Offset

### ***Distance X/Y/Z***

Adds a constant translation component to the duplicate object's offset. X, Y and Z constant components can be specified.

## Object Offset

Adds a transformation taken from a chosen object relative to the current object to the offset.

### ***Object***

Choose an object.

## Merge

If enabled, vertices in each copy will be merged with vertices in the next copy that are within the given Distance.

### ***Distance***

The merge distance between the vertices. Vertices below this distance will be merged.

### ***First and Last Copies***

Merge vertices in first and last duplicates.

## UV's

### ***Offset U/V***

Shifts UV's of each new duplicate by a settable amount.

## Caps

### Cap Start / End

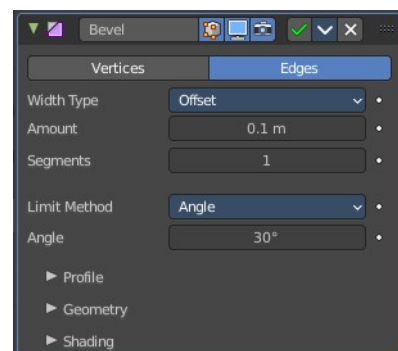

Adds a chosen mesh at the start and end of the array. The start object is added at position -1. The end object at position +1. When Merge is activated, and the cap vertices are within the Distance threshold, they will be merged.

Note! The start/end cap objects currently do not support the First and Last Copies option.

## Bevel

The Bevel modifier bevels the edges of the mesh. It is a non-destructive alternative to the Bevel Operation in Edit Mode.

## Affect

### Vertices

Only the areas near vertices are beveled, the edges remain unchanged.

### Edges

Bevels both edges and vertices.

## Width Type

Defines how Width will be interpreted to determine the amount of bevel.

### Offset

Value is interpreted as the distance from the original edge to the edge of the beveled face.

### Width

Value is interpreted as the distance between the two new edges formed by the bevel.

## **Depth**

Value is the perpendicular distance from the new bevel face to original edge.

## **Percent**

Similar to Offset but the value is interpreted as a percentage of the adjacent edge length.

## **Absolute**

Amount is absolute along adjacent edge.

## **Amount**

The bevel amount.

## **Segments**

The number of edge loops added along the bevel's face.

## **Limit Method**

Used to control where a bevel is applied to the mesh.

### **None**

No limit, all edges will be beveled.

### **Angle**

Only edges where the adjacent faces form an angle smaller than the defined threshold will be beveled. Intended to allow you to bevel only the sharp edges of an object without affecting its smooth surfaces.

### **Angle**

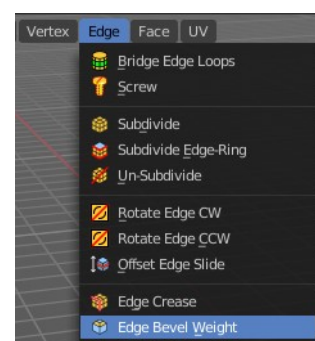

The angle above which to bevel.

### **Weight**

Use each edge's bevel weight to determine the width of the bevel. When the bevel weight is 0.0, no bevel is applied.

Edge bevel weight can be set in Edit mode in the Edge menu with the Edge Bevel Weight tool.

### **Vertex Group**

Use weights from a vertex group to determine the width of the bevel. When the vertex weight is 0.0, no bevel is applied. An edge is only beveled if both of its vertices are in the vertex group. See here about adjusting vertex group weights.

## Vertex Group

Choose the vertex group.

## Invert

Inverts the influence of the selected vertex group.

## Profile subpanel

The profile defines the shape of the bevel. Profile has no effect if the number of segments is below 2.

## Super Ellipse

Defines a rounded bevel corner.

## Shape

The shape of the rounded bevel corner. A value close to 0 bends the roundness to inside. A value towards 1 bends the curve to outside. A value of 0.5 defines a radius around the center point of the bevel.

## Custom

Here you can define a custom shape profile for the bevel.

## Miter Shape

The shape of the custom bevel corner. Has no effect when the miter type is sharp. You need to set it to Arc in the geometry section.

## Custom Profile

Choose and adjust a custom bevel profile. This feature needs more than one segment to work.

## Preset

Choose some profile presets.

## Zoom in

Zooms into the curve view.

## Zoom out

Zooms out of the curve view.

## Tools

### Reset View

Resets the zoom factor of the curve view.

### **Reset Curve**

Resets the curve to the defaults. This means when you choose a curve preset to reset it to the values of the latest chosen preset.

### **Reverse Path**

The path gets reversed. The first point becomes the last and vice versa.

### **Toggle Profile Clipping**

Toggles the profile clipping.

### **Curve view**

Adjust the profile curve.

Left click where no point is adds a new point. Left click at a point allows you to move it.

Holding down Shift while moving a node point activates precision movement.

Holding down ctrl while moving activates temporary snapping.

When a point is selected then the curve view reveals a sub menu at the bottom.

### **Handle Type *Auto Handle***

Sets the handle type of this curve point to smooth.

### **Handle Type *Vector Handle***

Sets the handle type of this curve point to sharp.

### **Handle Type *Free Handle***

Sets the handle type of this curve to Free handles. The curve point has now two handles with which you can adjust the curve before and after the point each.

### **Handle Type *Aligned Free Handle***

Sets the handle type of this curve to Free handles. The curve point has now a handle with which you can adjust the curve.

### **X Y Values**

The position of the currently selected curve point.

### **Delete**

Delete the selected curve point.

### **Sample Straight Edges**

Sample edges with vector handles.

### **Sample Even Lengths**

Sample edges with even lengths.

## Geometry subpanel

### **Miter Inner**

How the inner miter is set. Miter is how the bevel rounding at a corner is done.

#### **Sharp**

Creates a sharp miter.

#### **Arc**

This replaces the vertex of a miter with 2 vertices, joined by an arc. A separate Spread parameter says how far to move the vertices away from their original position.

### **Outer**

How the outer miter is set. Miter is how the bevel rounding at a corner is done.

#### **Sharp**

Creates a sharp miter.

#### **Patch**

This replaces the outside vertex of a miter with 3 vertices. And uses a patch pattern there.

#### **Arc**

This replaces the vertex of a miter with 2 vertices, joined by an arc. A separate Spread parameter says how far to move the vertices away from their original position.

### **Intersections**

If a bevel corner is filled or not. Needs minimum two segments to have effect.

When the inner corners of the cutoff profiles faces meet at the same location with a three way intersection, then no center face is created.

The direction of the cutoff faces depends on the original vertex's normal.

## ***Clamp Overlap***

Limits the width of each beveled edge so that edges cannot cause overlapping intersections with other geometry.

## ***Loop Slide***

If there are unbeveled edges along with beveled edges into a vertex, the bevel tries to slide along those edges when possible. Turning the option off can lead to more even bevel widths.

## **Shading subpanel**

## ***Harden Normals***

Match normals of new faces to adjacent faces.

Autosmooth needs to be enabled for this feature. And the shading needs to be smooth.

## ***Mark***

### **Seam**

When the beveled edge is a seam edge, then the bevel will also contain a seam to keep the seam into account.

### **Sharp**

When the beveled edge is a sharp edge, then the bevel will also contain a sharp edge to keep the sharp edge into account.

## ***Material Index***

The index of the material slot to use for the bevel. When set to -1, the material of the nearest original face will be used.

## ***Face Strength***

Set the Face Strength on the faces involved in the bevel by the mode specified here.

This face strength then can be used in conjunction with a following Weighted Normals modifier (with the Face Influence option checked).

### **None**

Do not set face strength.

**New**  
Set the face strength of new faces along edges to Medium, and the face strength of new faces at vertices to Weak.

**Affected**  
In addition to those set for the New case, also set the faces adjacent to new faces to have strength Strong.

**All**  
In addition to those set for the Affected case, also set all the rest of the faces of the model to have strength Strong.

## Boolean

The Boolean modifier uses one of the three available Boolean operations to create a single mesh out of two mesh objects. Union, Difference and Intersect. This modifier needs a second object to be the target of the operation.

Boolean operations may or may not deliver useful results. And requires nearly always manual cleanup afterwards since it tends to create N-Gon geometry and can create micro triangles. You should also avoid co-planar faces. Manifold meshes works best.

Tip! Tick Wireframe, and All Edges in the Viewport Display panel to see the bool result in realtime happen. And hide the bool object. That way you can tweak the positions of the objects if needed.

## Operation

The Boolean operation to use.

Demonstrated at a cube with the modifier applied, and a sphere as the target object.

### *Intersect*

Keeps the intersecting geometry, removes the non intersecting geometry.

### *Union*

The target mesh is added to the modified mesh.

## Difference

Keeps the non intersecting geometry, removes the intersecting geometry.

## Operand Type

### Object

The target mesh object. You need to choose a target mesh object for the boolean operation.

### Solver

Fast or Exact.

## Solver Options sub panel

### With solver method fast

#### Overlap Threshold

The threshold for overlapping geometry. This value determines above which value a boolean operation happens.

### With Solver Method Exact

#### Self Intersection

Allow self intersection in operand objects.

#### Hole Tolerant

Better results when the mesh contains holes.

## Build

The Build modifier lets the faces of the mesh object to appear or disappear one after the other over time when you play the animation.

By default, faces appear in the order in which they are stored in memory, which follows the order how they are created. This face/vertex order can

be altered in Edit Mode by using Sort Mesh Elements in the Mesh menu.

## Start

The start frame of the building process.

## Length

The number of frames over which to rebuild the object.

## Reversed

The modifier will operate in reverse, and start with the full mesh. And deconstruct it towards the end frame.

## Randomize

Randomizes the order in which the faces are built.

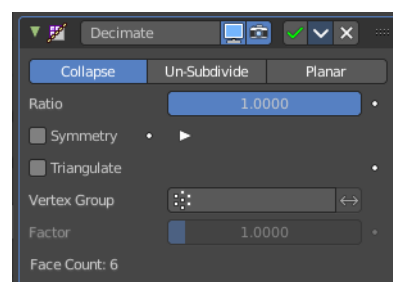

## Seed

The random seed. Changing this value gives a different “random” order when Randomize is checked. This order is always the same for a given seed/mesh set.

---

## Decimate

The Decimate modifier allows you to reduce the vertex/face count of a mesh with minimal shape changes. The result is just displayed in Object mode. In Edit mode the unaltered mesh is shown.

## Mode

### *Collapse*

This algorithm uses progressive merging of vertices, taking the shape of the mesh into account.

### Ratio

The ratio of faces to keep after decimation. 1.0 is not altered. The lower the value the stronger the reduction.

Note! Although the Ratio is directly proportional to the number of remaining faces, triangles are used when calculating the ratio.

This means that if your mesh contains quads or other polygons, the number of remaining faces will be larger than expected, because those will remain unchanged if their edges are not collapsed.

This is only true if the Triangulate option is disabled.

### Symmetry

Maintains symmetry on a single axis.

## **Triangulate**

Keeps any resulting triangulated geometry from the decimation process.

## **Vertex Group**

A vertex group that controls what parts of the mesh are decimated.

## ***Invert***

Decimate the geometry except the vertex group.

## ***Factor***

The influence factor of the vertex group.

## ***Un-Subdivide***

This algorithm tries to unsubdivide divided faces.

## **Iterations**

The number of times to perform the unsubdivide operation. Two iterations is the same as one subdivide operation, so you will usually want to use even numbers.

## ***Planar***

This algorithm reduces details by unioning adjacent faces that are below an angle limit.

## **Angle Limit**

Dissolve geometry which form angles (between surfaces) higher than this setting.

## **Delimit**

Prevent dissolving geometry in certain places.

## ***Normal***

Does not dissolve edges on the borders of areas where the face normals are reversed.

## ***Material***

Does not dissolve edges on the borders of where different materials are assigned.

## ***Seam***

Does not dissolve edges marked as seams.

## ***All Boundaries***

When enabled, all vertices along the boundaries of faces are dissolved.

## **Face Count**

The face count of the decimated mesh.

## Edge Split

The Edge Split modifier splits single edges into two independent edges when the adjacent faces are below the defined angle. Or when the edge is marked as sharp. Which can be done in edit mode in the Edge menu with the Mark Sharp tool.

Splitting an edge affects vertex normal generation at that edge, and makes the edge appear sharp. So this modifier can be used to achieve the same effect as Auto Smooth. And make edges appear sharp when their angle is above a certain threshold. It can also be used for manual control of the smoothing process, where the user defines which edges should appear smooth or sharp (see Mesh Smoothing for other ways to do this). If desired, both modes can be active at once.

Note! This modifier is kept mostly for historical/compatibility reasons. Everything it can do in shading, and much more, can now be achieved using custom normals. Unless you really need the topology changes it generates, it is not advised to use it in new projects.

## Edge Angle

The angle above which to split edges.

## Sharp Edges

When you have marked edges as sharp, then these edges will be split.

Note! Non-manifold edges will always be split.

---

## Mask

The Mask modifier allows to hide vertices of an object dynamically based on vertex groups or an Armature.

## Mode

Use Vertex Groups or an armature to hide the mesh Vertex Group works in Object mode. Armature works in Pose mode, and uses the active bone for masking.

## Vertex Group

Here you can select the vertex group that you want to use for masking. The geometry from this vertex group is shown.

## Smooth

Use vertex group weights to cut faces at the weight contour.

## Armature

When in Pose Mode, vertices belonging to the vertex group associated with the active bone (same names) will be visible. Vertices not in that group will be hidden.

## ***Invert***

Show the not selected geometry instead of the selected.

## **Threshold**

Vertices with weights less or equal to this value will be hidden.

---

## **Mirror**

The Mirror modifier mirrors a mesh along its local X, Y and/or Z axes, across the Object Origin. It can also use another object as the mirror center, then use that object's local axes instead of its own.

## **Workflow**

Usually this modifier is used for mirror modeling in edit mode. In Edit mode just the original side is editable then. Recommend is to remove half of the mesh before starting. The missing part will then be added by the Mirror modifier. But you can also use the Bisect feature.

## **Axis**

The axis to mirror along.

You can select more than one of these axes. And will then get more mirrored copies. With one axis you get a single mirror, with two axes four mirrors, and with all three axes eight mirrors.

## **Bisect**

If the mesh is already on both sides of the mirror plane, it is cut by that plane. And only one side (the “negative” one by default) is kept to perform the mirror process.

Note. When you turn Bisect on and pull at the mirror part, then you won't have the mirroring effect to the original side.

## **Flip**

When Bisect is enabled on an axis, you can use this setting to switch the side kept and mirrored (i.e. when it is enabled, the “positive” side will be kept, instead of the “negative” one).

## **Mirror Object**

An Object Selector to select an object (usually an empty), which position and rotation will be used to define mirror planes (instead of using the ones from the modified object).

You can animate it to move the mirror axis.

## Clipping

Prevents vertices from moving through the mirror plane(s) when you transform them in Edit Mode.

If it is enabled but vertices are beyond the mirror plane and outside of the Merge Distance, the vertices will not be merged. But as soon as the vertices are within Merge Distance they are snapped together and cannot be moved beyond the mirror plane.

Note! Vertices on the mirror plane will be unable to move away from the mirror plane as long as Clipping is enabled. You must disable it to be able to move the vertices along the mirror axis again.

## Merge

Where a vertex is in the same place (within the Merge Distance) as its mirror it will be merged with the mirrored vertex.

## Bisect Distance

Vertices are removed up to this distance from the bisect plane.

## Merge Distance

The maximum distance between a vertex and its mirror copy at which they are merged together (being snapped on the mirror plane). Needs Merge to be enabled.

## Data subpanel

### Mirror UV

Mirror the UV texture coordinates across the middle of the image.

### Offset UV

Mirrored UV Offset along u and v axis.

### Vertex Groups

Try to mirror existing vertex groups.

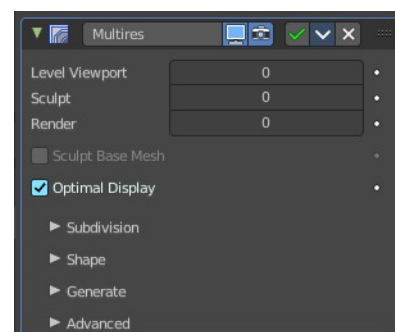

Note! The vertex groups you want to mirror must be named following the usual left/right pattern (i.e. with suffixes like “.R”, “.right”, “.L”, etc.). The mirror side vertex group must already exist (it will not be created automatically). It must also be completely empty (no vertices assigned to it).

### Flip UDIM

Mirror the texture coordinates around each tile center.

## Multiresolution

The Multiresolution modifier, in short “Multires”) allows you to subdivide a mesh similarly to the Subdivision Surface modifier, but also allows you to

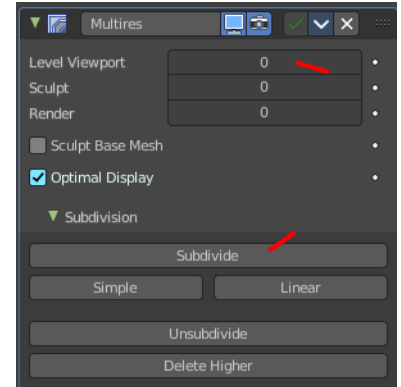

edit the new subdivision levels in Sculpt Mode.

Note! Multiresolution cannot be re-positioned in the stack after any modifier that will change geometry or other object data (This means all Generate, some Modify and some Simulate modifiers cannot come before the Multiresolution modifier). It needs to work at the unaltered base mesh.

## Workflow

Add the modifier. Switch to Sculpt mode. Click at the Subdivide button. The Levels sculpt slider will now turn to 1. Do some sculpting. Click at the Subdivide button again. The Levels sculpt slider will now turn to 2. You have added a second sds layer now. Do some sculpt now. Click at the Subdivide button again, and you have a third sds sculpting level. Do some sculpt now.

To work at level 1 SDS simply change the Levels sculpt value back to 1. Or to 2 when you want to work at layer 2.

---

## Level Viewport

Number of subdivisions in the viewport when not in sculpt mode.

## Sculpt

Number of subdivisions to use in sculpt mode.

## Render

Number of subdivisions when rendering the image.

## Sculpt Base Mesh

Sculpt at the base mesh, not at the multires sds layer. Note that this property is greyed out when you are not in sculpt mode.

## Optimal Display

In object mode the subdivided edges will not be drawn. Only the edges of the base geometry.

## Subdivision Subpanel

### *Subdivision Mode*

#### Subdivide

Adds another layer of subdivision. This subdivision method divides the mesh smooth with the catmull clark algorithm.

## Simple

Adds another layer of subdivision. The simple method just divides the existing faces.

## Linear

Adds another layer of subdivision. The linear method divides the existing faces and interpolates linear.

## Unsubdivide

Removes all subdivision layers.

## Delete Higher

Removes the highest subdivision layer.

---

## Shape subpanel

### Reshape

Copies vertex coordinates from another mesh.

Usage: first select a different mesh object with matching topology and vertex indices. Shift select the object you wish to copy vertex coordinates to. Click Reshape.

### Apply Base

Modifies the original unsubdivided mesh to match the form of the subdivided sculpted mesh.

---

## Generate Subpanel

Rebuild all possible sds levels to generate a lower resolution base mesh

### Save External

Saves displacements to an external .btx file. The Multiresolution sds information is then stored externally, so that the blend files doesn't become too big.

### File path

Once saved you will see the path to the btx file below the save external button. The save external button has turned into Pack external then.

## Type

Sets the type of subdivision. Note! You need to set the subdivision type before you start. You can't change it afterwards.

### Catmull-Clark

Creates a smoothed surface, using the standard Catmull-Clark subdivision surface algorithm.

## Simple

Maintains the current shape, and simply subdivides edges.

## Levels Sculpt

The subdivision layer.

## Viewport

Set the level of subdivisions to show in Object Mode. In Sculpt mode this value has no effect.

## Render

Set the level of subdivisions to show when rendering.

---

## Advanced Subpanel

### Quality

How precisely the vertices are positioned. This settings becomes active when you have an edge crease applied. This can be done in edit mode in the edge menu.

### UV Smooth

How to handle UV's during subdivision.

### Smooth, keep corners

UV islands are smoothed, but their boundary remain sharp.

### Sharp

UV remain unchanged.

### Use Creases

Use the crease information. This settings becomes active when you have an edge crease applied.

---

## Remesh

The Remesh modifier generates new mesh topology. The output follows the surface curvature of the input. But its topology contains quads.

The output and also the settings of the three basic modes Blocks, Smooth and Sharp is almost identical. Except the smoothing.

## Blocks, Smooth, Sharp

Blocks has no smoothing at all. Smooth outputs a smooth surface. Sharp outputs a smooth surface but preserves sharp edges and corners.

### ***Octree Depth***

The resolution of the Octree. Higher values gives finer details.

### ***Scale***

The ratio of the largest dimension of the model over the size of the grid.

### ***Sharpness***

Sharp mode only. Tolerance for outliers. Higher values produce edges more similar to the input, while lower values filter out noise.

### ***Remove Disconnected***

Filter out small disconnected pieces of the output.

### ***Threshold***

Use this to control how small a disconnected component must be to be removed.

### ***Smooth Shading***

Output faces with smooth shading. The smooth/flat shading of the input faces is not preserved.

## Voxel

Generate a new manifold mesh from the current geometry while trying to preserve the mesh's original volume.

### ***Voxel Size***

The voxel size. Defines the resolution of the created mesh.

### ***Adaptivity***

Reduces the final face count by simplifying geometry where detail is not needed. This feature triangulates faces that do not need as much detail.

### ***Smooth Shading***

Output faces with smooth shading. The smooth/flat shading of the input faces is not preserved.

## Screw

The Screw modifier takes a profile object, a mesh or a curve, to create a helix-like shape.

The profile should be properly aligned to the cardinal direction of the object.

### Angle

Degrees for a single helix iteration.

### Screw

Offsets the iteration along its axis.

### Iterations

Number of iterations.

### Axis

The axis along which the helix will be built.

### Screw

The height of one helix iteration.

### Axis Object

Pick an object to define the axis direction. The helix will then point into the direction of this object.

### Object Screw

Use the distance from the Axis Object to define the height of one helix iteration.

### Steps Viewport

Number of steps used for a single revolution displayed in the 3D Viewport.

### Render

Number of steps used for a single revolution used during render time. Higher values gives higher quality.

### Merge

Merge vertices that lie on the axis of rotation. Closes off end points with a triangle fan.

### Merge Distance

Vertices under this distance to the axis are merged.

### Stretch UV's

Stretch the UV coordinates from (0.0 to 1.0) when UV's are present.

## Normals

### **Smooth Shading**

Output faces with smooth shading. The smooth/flat shading of the input geometry is not preserved.

### **Calculate Order**

Order of edges is calculated to avoid problems with normals and shading. Only needed for meshes, not curves.

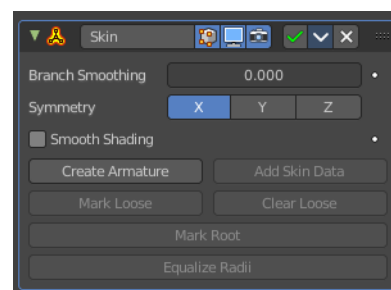

### **Flip**

Flip normals direction.

## Skin

The Skin modifier uses vertices and edges to create a skinned surface. The output is mostly quads. But intersections can also produce triangles.

You can use geometry with faces as the base geometry. But the modifier just uses the vertices and edges information.

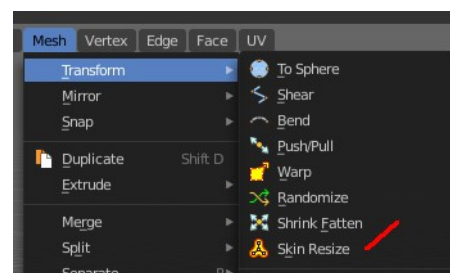

Note! Faces in the original geometry are ignored. The modifier works with the edges and vertices of the geometry. The faces of a cube for example gets removed. The new geometry appears around the edges.

Note! The thickness of the created geometry can be adjusted in Edit mode with the Skin Resize tool.

Note! The Edit mode also activates most of the in Object mode greyed out tools.

## Branch Smoothing

A branch point is a vertex with three or more connected edges. These areas tend to produce more complicated topology, some of which may overlap. This setting relaxes the surface around these points, with the side effect of shrinking it.

## Symmetry Axes X/Y/Z

Keep the output topology symmetrical in their here chosen axes.

Note! They do not add geometry flipped across an axis. For that, the Mirror modifier should be used, typically placed above the Skin modifier.

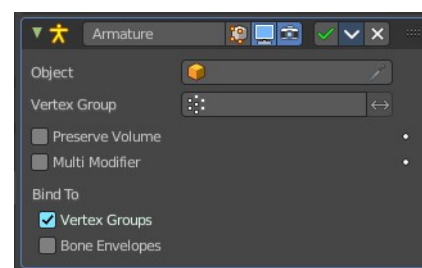

## Smooth Shading

Output faces with smooth shading rather than flat shading. The smooth/flat shading of the input geometry is not preserved.

## Create Armature

Creates an armature modifier below the Skin modifier. Each edge becomes a bone. And the generated mesh of the Skin modifier is assigned to this armature, with automatic weights. Deforming the armature will then deform the mesh.

Note! If the root vertex has more than one adjacent edge, an extra bone will be created to serve as the root.

## Add Skin Data

The Skin modifier uses a custom set of data in the mesh. This data is generated automatically when you add the Skin modifier the first time. There are use cases where this data can get lost, and the Skin modifier quits working. Add Skin Data then becomes available, and you can update the data.

## Mark / Clear Loose

You need to be in Edit Mode to make this tool active.

By default, a branch vertex (vertex with three or more connected edges) will generate extra edge loops along adjacent edges in order to keep the output tight. Branches can be made loose by clicking Mark Loose, which will allow the output to stretch between all adjacent vertices. This can be disabled again by clicking Clear Loose.

## Mark Root

You need to be in Edit Mode to make this tool active.

Marking a vertex as root causes that vertex to be used for calculating rotations for connected limbs. Root vertices also affect the armature output, they will be used as the origin for the root bones.

Each set of connected vertices should have one root node (one is selected by default if you do not assign any manually). Mark Root enforces the one-root per set rule, so it is not necessary to manually unmark roots.

## Equalize Radii

You need to be in Edit Mode to make this tool active.

Makes the skin radii of selected vertices equal on each axis.

## Solidify

The Solidify modifier adds depth and thickness to the faces of a geometry.

Example. A cube with one face removed.

### Mode

#### Simple

This algorithm simply extrudes the geometry. It does not work on geometry where edges have more than two adjacent faces.

Important! Simple mode will not be able to solidify the boundary between two adjacent faces that does not point into the same direction.

### Thickness

The extrude amount.

### Offset

A value between (-1 to 1) to locate the solidified output inside or outside the original mesh. The inside and outside is determined by the face normals. Set to 0.0, the solidified output will be centered on the original mesh.

### Even Thickness

Maintain the thickness by adjusting for sharp corners.

Note! Solidify thickness is an approximation. The final wall thickness is not guaranteed. The best option to preserve wall thickness is complex mode with constraints thickness mode. But even this is not guaranteed to work perfect in every case.

## Fill Rim

Fills the gap between the inner and outer edges.

Note! Fill Rim and Only Rim only make a difference on Non-manifold objects, since the rims are generated from the borders of the original geometry.

## Only Rim

Will not extrude surfaces parallel to the original one, but instead will only add the perpendicular rim.

## Complex

This solidify algorithm can handle every geometric situation to guarantee a manifold output geometry. It is able to solidify shapes like Möbius strips, Klein bottles, architectural wall layouts and many more which the Simple Mode isn't able to do.

If the special cases are not present it is recommended to choose Simple because the extra logic makes this algorithm much slower.

Note! There are no options for crease in the Modifier tab because crease is handled in a dynamic way. The modifier will transfer the creases of the original mesh in a smart way to the output mesh to work with the Subdivision Surface modifier.

## Thickness Mode

Choose the kind of thickness handling.

### Fixed

The new vertices are always in a fixed distance to the old ones.

### Even

Adjusts for sharp corners, but may not always work when more than three faces come together.

### Constraints

For up to three faces it is always guaranteed to find an optimal solution.

## Boundary

Choose the kind of boundary handling.

### None

No boundary fix is applied. Results are stable.

### Round

Adjusts the boundary for an opening to face inwards (like a hole in an egg).

### Flat

Adjusts the boundary of a planar opening to be a flat (like a cut sphere).

## Thickness

The extrude amount.

Important! The modifier thickness is calculated using local vertex coordinates. If the object has a non-uniform scale, the thickness will vary on different sides of the object. To fix this, either Apply or Clear the scale.

### **Offset**

A value between (-1 to 1) to locate the solidified output inside or outside the original mesh. The inside and outside is determined by the face normals. Set to 0.0, the solidified output will be centered on the original mesh.

### **Merge Threshold**

The distance within which degenerated geometry is merged.

### **Rim**

Note! Fill and Only Rim only make a difference on Non-manifold objects, since the rims are generated from the borders of the original geometry.

#### ***Fill Rim***

Fills the gap between the inner and outer edges.

#### **Only Rim**

Will only leave the generated perpendicular rim

Note! Fill and Only Rim only make a difference on Non-manifold objects, since the rims are generated from the borders of the original geometry.

### ***Vertex Group***

Only vertices in this group are solidified. Their weights are multiplied by the thickness, so vertices with lower weights will be less thick.

### **Invert**

Reverses the vertex group, so that only vertices which are not in the vertex group are solidified.

### **Factor**

How much the vertex weights are taken into account. You need to have a vertex group assigned to activate this item.

On 0.0, vertices with zero weight will have no thickness at all (creates duplicate vertices).

On 0.5, vertices with zero weight will be half as thick as those with full weight.

On 1.0, the weights are ignored and the Thickness value is used for every vertex.

### ***Flat Faces***

Just in Complex Mode. Use the minimal vertex weight assigned to the vertices of a face to make sure that new faces stays parallel to their original ones. This is slow, so disable it when it is not needed.

### ***Normals***

#### **Flip Normals**

Reverse the normals of all geometry (both the inner and outer surfaces).

## High Quality Normals

Just Simple Mode. Normals are calculated to produce a more even thickness.

## Materials

### Material Offset

Choose a different material for the new geometry. This is applied as an offset from the original material of the face from which it was solidified.

A value of 0 means it will use the same material.

A value of 1 means it will use the material immediately below the original material.

A value of -2 means the material two positions above the original material will be used.

These values are clamped to the top-most and bottom-most material slots.

### Rim

Choose a different material for the rim faces.

## Edge Data

Inner, Outer and Rim are simple mode only.

### Inner

Set a crease to the inner edges.

### Outer

Set a crease to the outer edges.

### Rim

Set a crease to the rim.

### Bevel Convex

Edge bevel weight to be added to outside edges.

## Thickness Clamp

### Clamp

A value between (0 to 2) to clamp offsets to avoid self-intersection. The amount is determined by the length of the shortest adjacent edge.

### Angle Clamp

If enabled clamping will also consider angles in the geometry, not only lengths. Becomes active when the clamp value is above 0.0.

## Output Vertex Groups

### Shell

Vertex group that the generated shell geometry will be weighted to. This

allows you to use other modifiers to only affect the shell geometry by using a that modifier's vertex group influence control.

## Rim

Same as Shell Vertex Group, but for the generated rim geometry.

## Subdivision Surface

The Subdivision Surface modifier subdivides the faces of the mesh. With Simple it just divides the faces. The Catmull-Clark algorithm allows you to smoothen the result.

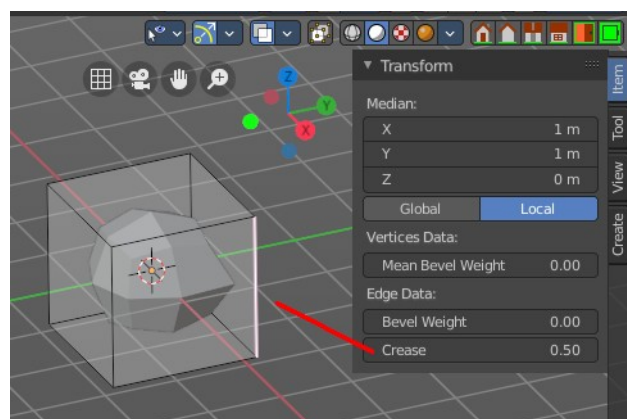

## Type

### Catmull-Clark

Subdivides and smooths the surfaces.

Note! Catmull-Clark subdivision rounds off edges. And sometimes this is not what you want. There are several solutions that allow you to control the subdivision. You can add a so called support edge or a support loop to keep the edge sharp.

Or you can change the crease of the edges in question. Edge Crease can be adjusted in the Transform panel in the Item tab of the sidebar in the 3D view. You need to be in Edit mode.

Note! Abrupt normal changes in the surface can produce ugly black gouges, even when these flipped normals are not an issue for the shape itself. A quick way to fix this is to use the Recalculate Normals operation in Edit Mode. If you still have some ugly black gouges you can try to manually flip the normals in question.

### Simple

Only subdivides the surfaces, without any smoothing.

## Levels Viewport

The number of subdivision levels shown in the 3D Viewport.

## Render

The number of subdivision levels shown in the final render.

## Optimal Display

When rendering the wire frame of this object, the wires of the new subdivided edges will be skipped. Only the edges of the original geometry will be displayed.

## Advanced

### Quality

How precisely the vertices are positioned, relatively to their theoretical position of an infinitely subdivided mesh.

Note! This value can have an affect on how accurate Edge Creases can be. Using a higher Quality value will allow for a wider range of crease values to work accurately.

### UV Smooth

How to handle UV's during subdivision.

#### None

Uvs are not smoothed, boundaries are kept sharp.

#### Keep Corners

UV's are smoothed, corners on discontinued boundaries are kept sharp.

#### Keep Corners, Junctions

UV's are smoothed, corners on discontinued boundaries are kept sharp. And conjunctions of three or more regions are kept sharp.

#### Keep Corners, Junctions, Concave

UV's are smoothed, corners on discontinued boundaries are kept sharp. And conjunctions of three or more regions and darts and concave corners are kept sharp.

#### Keep Boundaries

UV's are smoothed, boundaries are kept sharp.

#### All

UV's and boundaries are smoothed.

#### Smooth, keep corners

UV islands are smoothed, but their boundary remain sharp.

#### Sharp

UV remain unchanged.

### Boundary Smooth

#### Keep Corners

Smooth boundaries, but corners are kept sharp.

#### All

Smooth boundaries, including corners.

## **Use Creases**

Use the Weighted Edge Creases values stored in edges to control the smoothness of the edges.

## **Use Custom Normals**

Interpolates existing custom normals to resulting mesh.

---

## **Triangulate**

The Triangulate modifier triangulates all faces in a mesh.

### **Quad Method**

How to triangulate quads.

#### **Beauty**

Tries to split the quads in a way that takes the topology into account.

#### **Fixed**

Split the quads on their 1st and 3rd vertices.

#### **Fixed Alternate**

Split the quads on their 2nd and 4th vertices.

#### **Shortest Diagonal**

Split the quads based on the diagonal distance between their vertices.

### **N-Gon Method**

How to triangulate N-Gons.

#### **Beauty**

Tries to split the N-Gons in a way that takes the topology into account.

#### **Clip**

Split the N-Gons by using an ear-clipping algorithm

### **Minimum Vertices**

Minimum number of vertices a face must have to be triangulated. For example, setting this value to 5, will prevent triangulation of Quads and only triangulate N-gons.

## Volume to mesh

This modifier is the inverse of the Mesh to Volume modifier. It takes an existing volume object and converts one of its grids to a mesh. Only scalar grids (such as the density grid) can be converted.

Tip! To copy and move the generated mesh separately from the volume object, use a collection instance.

### Object

The source volume object. Pick the volume object here.

### Grid Name

The name of the grid to convert. The grid has to be a scalar grid.

### Resolution Mode

How the resolution of the final mesh is controlled.

### *Grid*

This makes the resolution dependent on the resolution of the grid that is converted. Higher resolution grids result in a higher resolution mesh. In many cases, that is the most efficient mode.

### *Voxel Amount*

Specifies the approximate resolution of the final mesh. The voxel size is adapted to the size of the entire volume.

### *Voxel Size*

Use a fixed resolution that does not change when the volume changes.

### Threshold

Voxels with a larger value are considered to be inside the mesh and all other voxels outside. The mesh will be generated on the boundary of inside and outside voxels. This is sometimes also called the “iso value”.

### Adaptivity

This is similar to decimating the final to reduce resolution where it is not needed.

### Smooth Shading

Enables smooth shading on the generated mesh.

## Weld

The Weld modifier merges vertices within a threshold.

### Mode

#### *All*

Full merge by distance.

#### *Connected*

Just along the edges.

### Distance

The maximum distance to merge vertices.

### Only Loose Edges

Just with Connected. Welds only loose edges.

### Vertex Group

Only merge vertices from this vertex group.

### *Invert*

Inverts the influence of the selected vertex group. Only vertices outside of this vertex group will be merged.

## Wireframe

The Wireframe modifier hides the faces of a mesh, and turns the edges into four sided polygon geometry. The result then looks like you would have a wire frame view of the mesh.

The mesh needs to have faces.

### Thickness

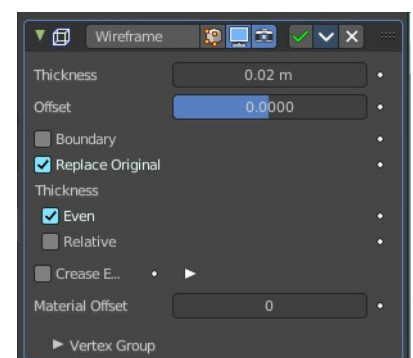

The depth or size of the wire frames.

### Offset

A value between (-1 to 1) to change whether the wire frames. are generated inside or outside of the original mesh. Set to zero, Offset will center the wire frames. around the original edges.

### Boundary

Creates wire frames. on mesh island boundaries.

## Replace Original

Replace the original mesh by the generated wire frame mesh. If not, the wire frame is generated on top of it.

## Thickness

Warning! Wireframe thickness is an approximation. While Even Thickness should yield good results in many cases, skinny faces can cause ugly spikes. In this case you can either reduce the extreme angles in the geometry or disable the Even Thickness option.

### *Even*

Maintain thickness by adjusting for sharp corners. Sometimes improves quality but also increases computation time.

### *Relative*

Determines the edge thickness by the length of the edge. Longer edges will be thicker.

## Crease Edges

This option is intended for usage with the Subdivision modifier. Enable this option to crease edges on their junctions and prevent large curved intersections.

## Crease Weight

Define how much crease (0 to 1, nothing to full) the junctions should receive.

## Material Offset

Uses the chosen material index as the material for the wire frame; this is applied as an offset from the first material.

## Vertex Group

Restrict the modifier to only this vertex group, and use its weighting for thickness.

### *Invert*

Inverts the vertex group weights.

### *Factor*

Percentage that the vertex has influence over the final wire frame result.

---

## Mesh to Volume

You need a volume object.

The Mesh to Volume modifier uses a mesh to create a new volume grid. All previously existing volume grids on the volume object are discarded. So this modifier is usually added to an empty volume object. The new volume grid is called “density”.

Tip! To copy and move the generated volume separately from the mesh object, use a collection instance.

## Object

The mesh object to use for the volume generation. Pick a mesh object here.

## Density

Makes the generated volume appear denser or less dense when rendering.

## Fill Volume

The entire enclosed volume or otherwise only the voxels close to the surface will get a density greater than zero. This setting is only used when the mesh object is Manifold.

## Exterior Band Width

The maximum distance of the included voxels to the surface on the outside of the mesh.

## Interior Band Width

The maximum distance of the included voxels to the surface on the inside of the mesh. Activating Fill Volume is similar to increasing the interior band width to a high number.

## Resolution Mode

Mode for how the voxel size is specified.

### *Voxel Amount*

This allows setting an approximate number of voxels that will be used to represent mesh along its diagonal. When the dimensions of the mesh changes, the voxel size will change as well. For final rendering of animations, it's better to specify the voxel size explicitly to avoid artifacts.

### *Voxel Size*

This allows setting the exact voxel size that will be used. This is idea for rendering when the voxel size should not change between frames.

## Armature

An armature system allows to deform objects accurately by posing bones. The Armature modifier contains the armature settings at the mesh end.

This modifier gets created automatically when you parent a mesh to an armature.

## Object

The name of the armature object used by this modifier.

## Vertex Group

A vertex group of the object, which weights will be used to determine the influence of this modifier's results when mixing it with the results from other Armature ones.

This is only of use when having at least two of these modifiers on the same object, with Multi Modifier activated.

## Invert

Inverts the influence set by the vertex group.

## Preserve Volume

Use quaternions for preserving volume of object during deformation.

Without Preserve Volume, rotations at joints tend to scale down the neighboring geometry, up to nearly zero at 180 degrees from rest position. With it, the geometry is no longer scaled down, but there is a discontinuity when reaching 180 degrees from rest position.

## Multi Modifier

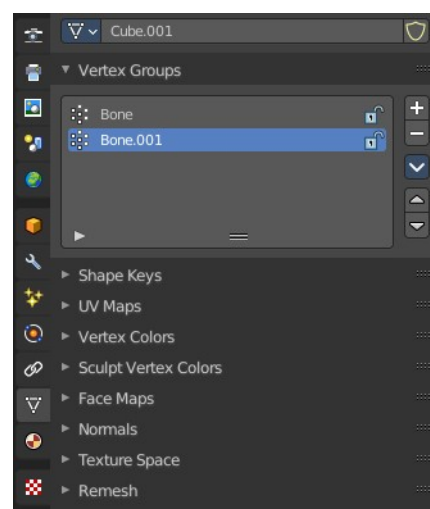

You can parent an object to more than one armature. The Multi Modifier allows you to use several armatures to deform the same object, all based on the “non-deformed” data.

The results of the Armature modifiers are then mixed together, using the weights of the Vertex Group as “mixing guides”.

## Bind to

### Vertex Groups

Meshes and lattices only. Use Vertex groups for deforming the mesh. A bone named “forearm”, will only affect the vertices in the “forearm” vertex group. The influence of one bone on a given vertex is controlled by the weight of this vertex in the relevant group.

The vertex groups are located in the Object Data Properties in the Properties editor.

## Bone Envelopes

Use the Bone envelopes to deform vertices or control points near them, defined by each bone's envelope radius and distance.

When envelopes are disabled, Blender uses the set of existing vertex group names to determine which bones influences what mesh part.

Bone envelopes display can be turned on in the Viewport Display panel in the Object Data properties tab in the Properties Editor. Display as ...

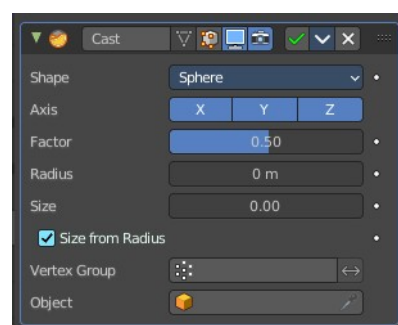

And can be adjusted in the Transform panel in the sidebar of the 3D View, in Edit mode.

## Cast

The Cast modifier shifts the shape of a mesh, curve, surface or lattice object, towards predefined shapes. Sphere, cylinder, cuboid.

Note! For performance reasons, this modifier only works with local coordinates. If the modified object looks wrong, you may need to apply its transformations, especially when casting to a cylinder.

## Shape

Choose the target shape of the projection: Sphere, Cylinder or Cuboid.

## Axis

The directions in which the modifier works. For a Cylinder shape the Z axis remains unaffected.

## Factor

The factor to control blending between original and cast vertex positions.

The factor is a linear interpolation. 0.0 gives original coordinates, and the modifier has no effect then. 1.0 casts to the target shape. Values below 0.0 or above 1.0 exaggerate the deformation.

## Radius

A value above 0.0 defines a sphere of influence. Vertices outside it are not affected by the modifier.

## Size

Alternative size for the projected shape. If zero, it is defined by the initial shape and the control object, if any.

## Size from Radius

Calculate Size from Radius. Can give smoother results.

## Vertex Group

Restrict the effect to the vertices in that vertex group.

## Invert

Inverts the influence of the selected vertex group.

## Object

The name of an object to control the effect. The location of this object's origin defines the center of the projection. And its size and rotation transform the projected vertices.

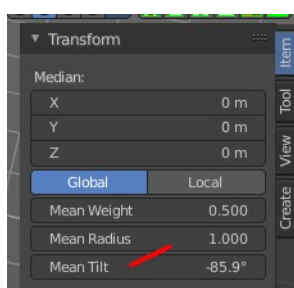

## Curve

The Curve modifier deforms a mesh along a curve object. You need to have a curve object in the scene, and choose it as the curve object.

The modifier works in global space on a dominant axis, X, Y, or Z. When you move your mesh in the dominant direction, the object will move along the curve. When you pull into the other axis directions then the object will move away from the dominant axis, and deform.

When you move the object beyond the curve's ends, the object will keep the deformation from the latest curve point.

If the curve is 3D, then the rotation of the object can be controlled by the mean tilt of the curve control points. The mean tilt can be found in edit mode in the sidebar in the Transform panel. Other options in the Shape panel can also have

an influence at the deforming result. Like Stretch.

## Curve Object

The name of the curve object that will affect the deformed object.

## Deformation Axis

The axis to deform along.

## Vertex Group

Restrict the effect to the vertices in that vertex group.

## Invert

Inverts the influence of the selected vertex group.

---

## Displace

The Displace modifier displaces vertices in a mesh based on the greyscale values of a texture. You can use image textures or procedural textures.

## Workflow

Create a texture. Switch to the Texture tab. Load an image texture, or change the type to any procedural image type that fits your needs. Like Clouds.

## Texture

The name of the texture from which the displacement for each vertex is derived. If this field is empty, the modifier defaults to 1.0 (white).

---

## Texture Prop

### Texture browser

A list of the available textures

### Texture Edit Box

The name of the currently active texture. Allows to rename the texture too.

## Fake User

Keep this data even when it has no user in the scene.

## Add Texture

Add a new texture.

## Remove

Removes the texture. Note that the texture is still in the browser list.

## Change Context

Jump to texture tab and show the texture.

---

## Coordinates

The texture coordinate system to use for the displacement.

The displacement can be along a particular local axis, along the vertex normal. Or the separate RGB components of the texture can be used to displace vertices in the local X, Y and Z directions simultaneously. This is called Vector Displacement.

## Direction

The direction along which to displace the vertices.

### X, Y, Z

Displace along an axis.

### Space

With a direction set to X, Y, Z, or XYZ the modifier can either displace along local or global axes.

### Normal

Displace along the vertex normal.

### Custom Normal

Displace along (averaged) custom normals, instead of vertex normals.

### RGB to XYZ

Displace along local XYZ axes individually using the RGB components of the texture. Red values displaced along the X axis, Green along the Y, Blue along the Z axis.

### Space

With a direction set to X, Y, Z, or XYZ the modifier can either displace along local or global axes.

## Strength

The strength of the displacement. A negative strength inverts the effect of the modifier.

After offsetting by the Mid level value, the displacement will be multiplied by the Strength value to give the final vertex offset.

$\text{vertexoffset} = \text{displacement} \times \text{Strength}$

## Mid level

The texture value which will be treated as no displacement by the modifier. Texture values below this threshold will result in negative displacement along the selected direction, while texture values above it will result in positive displacement.

$\text{displacement} = \text{texturevalue} - \text{Midlevel}$

Note that that color/luminosity values are typically between (0.0 to 1.0) in Blender, and not between (0 to 255).

## Vertex Group

Use a vertex group to control the influence of the modifier.

### *Invert*

Inverts the influence of the selected vertex group.

## Hook

The Hook modifier is used to deform a mesh, curve or lattice by another object. When you move this hook object, then it pulls vertices or control points with it.

Assigning the hook object to specific vertices of the target object is done in Edit mode. The modifier shows a set of buttons then.

This modifier is automatically created when you add a Hook from the Hooks menu in the Edge menu in edit mode.

Some settings just exists in Edit mode.

Warning! The Hook Modifier stores vertex indices from the original mesh to determine what to affect. Modifiers that generate geometry, like Subdivision Surface, should always be put after the Hook modifier in the stack. Otherwise, the generated geometry can't be affected by the hook's influence.

### Object

The name of the object to hook vertices to.

### Vertex Group

Allows you to define the influence per vertex.

### *Invert*

Inverts the influence of the selected vertex group.

## Strength

Adjust this hooks influence on the vertices.

## Reset

In Edit mode. Recalculate and clear the offset transform of the hook.

## Recenter

In Edit mode. Set the hook center to the 3D cursor position.

## Select

In Edit mode. Select the vertices affected by this hook.

## Assign

In Edit mode. Assigns selected vertices to this hook.

## Falloff

### Type

This can be used to adjust the kind of influence curve that the hook has on the mesh. You can also define a custom curve to get a much higher level of control.

### Radius

The size of the hooks influence.

### Uniform Falloff

Compensate non uniform scale, and use a uniform falloff.

## Laplacian Deform

The Laplacian Deform modifier allows you to pose a mesh by using some anchor vertices and moving them around. The modifier takes care for a proper deformation of the rest of the vertices.

This modifier needs a hook modifier to move the geometry.

Note! With a dense mesh above 100k the algorithm may fail.

## Workflow

Switch to Edit mode. Create a single vertex group, and add the vertices that you want to use as the anchor areas.

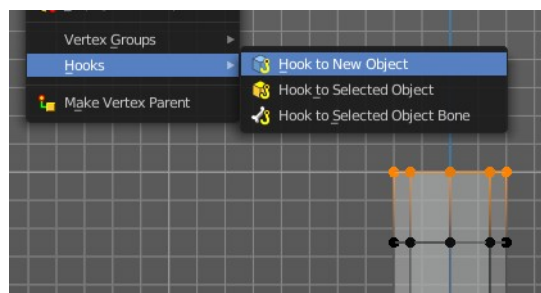

You need at least two anchor areas.

Add a hook to each of this anchor areas. In our case one to the top of the cylinder, and one to the bottom of the cylinder.

I add the hook by Hook to New Object from the Vertex menu here, which creates an empty.

You should now have two hook objects in the modifier stack of the cylinder. And two empties.

Switch back to object mode. Select the cylinder. Add a Laplacian Deform modifier. In the Anchor Weights edit box select the vertex group that we have created.

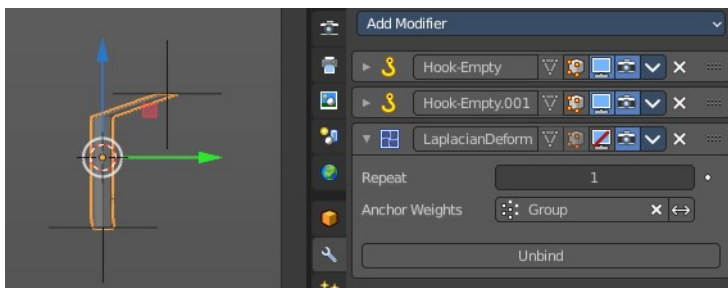

Click at Bind to bind the vertex group to the modifier. Note! Binding happens with the current deformation. Not to the unmodified base mesh. When you have moved the hooks already to deform the mesh, then this will be the base for the calculation.

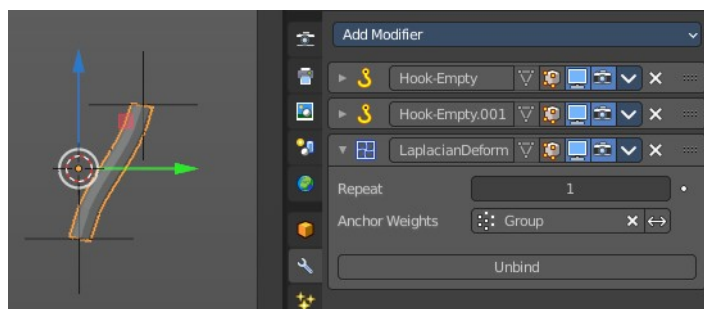

Now move the hooked empties.

Without the Laplacian deform modifier moving the hooked empties will now only pull the vertices that are hooked.

With the Laplacian deform modifier the deformation affects all geometry, which allows you to pose the mesh. The algorithm tries to interpolate the result to give the best possible fitting deformation.

## Repeat

How many iterations to use to improve the deformation. More iterations improves detail and calculation time.

## Anchor Weights

The group of vertices to use for the transformation. The weight of each vertex does not affect the behavior of the modifier. The method only calculates vertices with a weight greater than 0.

## Invert

Inverts the influence of the selected vertex group.

## Bind

Bind the vertex group to the modifier. Note! Binding happens with the current deformation. Not to the unmodified base mesh. When you have moved the hooks to deform the mesh, then this will be the base for the calculation.

## Unbind

Unconnect the vertex group from the modifier.

## Error Messages

### ***Vertex group group\_name is not valid***

This message is displayed when a user deletes the vertex group or changes its name.

### ***Vertices changed from X to Y***

This message is displayed when a user adds or deletes vertices to/from the mesh.

### ***Edges changed from X to Y***

This message is displayed when a user adds or deletes edges to/from the mesh.

### ***The system did not find a solution***

This message is displayed if the solver could not find a solution.

---

## Lattice

The Lattice modifier deforms the base object by the shape of a Lattice object. It can be used at meshes, curves, surfaces, text, lattices and even particles.

A Lattice modifier with valid settings can be added by selecting the object, holding down shift, select the target lattice object, and then choose Lattice Deform in the Parent menu.

Note! When you want to use a lattice to deform particles, then you need to place the Lattice modifier after the Particle System modifier.

## Object

The Lattice object that deforms the base object.

## Vertex Group

Limit the modifier's effect to a vertex group of the base mesh.

## ***Invert***

Inverts the influence of the selected vertex group.

## **Strength**

A factor to control blending between original and deformed vertex positions.

---

## **Mesh Deform**

The Mesh Deform modifier allows an arbitrary mesh of any closed shape to act as a deformation cage around another mesh.

Note! The changes are not displayed in edit mode. But Edit mode is where you deform your cage object.

Note! This modifier can run out of memory and crash.

## **Object**

The name of the mesh object to be used as the deforming cage.

## **Vertex Group**

Restrict the affected vertices to a vertex group.

## ***Invert***

Inverts the influence of the selected vertex group.

## **Precision**

Controls the accuracy with which the deform mesh cage alters the deformed object when the points on the cage are moved. Higher values means better precision and higher calculation time.

This setting is unavailable once a cage has been bound.

## **Dynamic**

When activated, other mesh altering features (such as other modifiers and shape keys) are taken into account when binding. This increases the deformation quality.

This setting is unavailable once a cage has been bound.

## **Bind**

Bind the current vertex positions of both, the modified geometry and the deforming Object, together. An unbound Mesh Deform modifier has no effect. It must be bound so that altering the shape of the deform mesh cage is able to alter the shape of the modified object.

Warning! It can take a long time for the operation to complete. And the software may not respond for a pretty while.

## Unbind

Unbind the meshes. The deformed object will reset back to its original shape that it had before it was bound to the deform mesh cage.

## Shrinkwrap

The Shrinkwrap modifier allows an object to “shrink” to the surface of another object. It moves each vertex of the object to the closest position on the surface of the target object.

It can be applied to meshes, lattices, curves, surfaces and texts.

## Wrap Method

The method to determine the nearest point on the target’s surface for each vertex of the object.

### *Nearest Surface Point + Target Normal Project*

Nearest Surface Point selects the nearest point at the surface. Additionally, Target Normal Project tries to match the interpolated normals of the surface.

## Snap Mode

How the vertex snaps to the surface. The methods should be self explaining.

## Target

The target mesh to shrink to.

## Project

Projects all vertices along a chosen axis until they hit the surface of the target object.

Vertices that never hits the surface are not calculated.

## Snap Mode

How the vertex snaps to the surface. The methods should be self explaining.

## Limit

A distance limit between original vertex and surface. If the distance is larger than this limit vertex would not be projected onto the surface.

## Subdivision Levels

This applies a (temporary) Catmull-Clark subdivision to the modified object's geometry, before computing the wrap.

## Axis

Along which local axis of the modified object the projection is done. These options can be combined with each other, yielding a "median axis" of projection. If none are selected, the normal direction is used.

## Negative/Positive

This allows you to select the allowed direction(s) of the shrink along the selected axis. If both options are enabled, both ways are evaluated and the closest hit is selected.

## Face Cull

Allows you to prevent any projection over the "front side" or the "back side" of the target's faces. The "side" of a face is determined by its normal.

## Invert Cull

When projecting in the negative direction then invert culling.

You need to have negative ticked and face cull either front or back to set this property active.

## Target

The target mesh to shrink to.

## Auxiliary Target

An additional object to project to.

---

## Nearest Vertex

Snaps to the nearest vertex instead of the nearest surface point.

## Target

The target mesh to shrink to.

---

## Offset

An offset distance to keep to the target surface.

## Vertex Group

Restrict the affected vertices to a vertex group.

## ***Invert***

Inverts the influence of the selected vertex group.

## **Simple Deform**

The Simple Deform modifier allows simple deforming of an object of type Mesh, lattice, curve, surface and text.

The deformation is calculated in local coordinate space.

## **Deform Method**

### ***Twist***

Twist rotates the object around an axis. Vertices in the same plane as the origin are not rotated. Above the origin the rotation is clockwise. Below the origin the rotation is negative. The amount of rotation is dependent of the distance to the origin. Closer vertices rotates not so strong.

### ***Bend***

Bend bends the object over an axis.

### ***Taper***

Taper tapers the object across its origin. The scaling factor is weighted by the distance from the origin of the object in the deform axis.

### ***Stretch***

Stretch scales the object along an axis.

Angle (Twist & Bend) / Factor (Taper & Stretch)

The total amount of deformation. A negative value reverses the deformation.

## **Origin**

Pick an object to use its origin as the origin for the simple deformation.

## **Restrictions**

### ***Limits***

You can set lower and upper limits for the deformation. The upper limit cannot be lower than the lower one. These limits are mapped on the Deform axis.

### ***Lock***

Not for Bend. Do not allow deformations along these axis.

## ***Vertex Group***

Limit the deformation to a vertex group.

---

## **Smooth**

The Smooth modifier smoothens a mesh by flattening the angles between adjacent faces.

### **Axis**

The axis to modify.

### **Factor**

The smoothing amount. Higher values will increase the effect. Values outside expected range (above 1.0 or below 0.0) will distort the mesh.

### **Repeat**

The number of smoothing iterations.

### **Vertex Group**

Limit the modifier to a vertex group.

### ***Invert***

Inverts the influence of the selected vertex group.

---

## **Smooth Corrective**

The Smooth Corrective modifier tries to reduce highly distorted areas of a mesh. Like an armature with distortions at bent knees.

### **Factor**

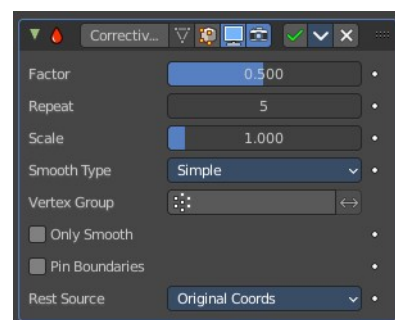

The factor to control the smoothing amount. Higher values will increase the effect. Values outside expected range (above 1.0 or below 0.0) will distort the mesh.

### **Repeat**

The number of smoothing iterations, equivalent to executing the Smooth tool multiple times.

### **Scale**

Additional scaling factor to increase the size of the mesh. This is useful because sometimes the Smooth Corrective modifier will introduce volume loss, especially when used with a rig.

## Smooth Type

The smoothing method.

### *Simple*

Relaxes vertices to their connected edges.

### *Length Weight*

Weights by the distance of surrounding vertices. This option can give higher quality smoothing in some cases, by better preserving the shape of the original form.

## Vertex Group

Restrict the effect to a vertex group.

### *Invert*

Inverts the influence of the vertex group.

## Only Smooth

Preview the smoothing used, before correction is applied.

## Pin Boundaries

Prevent boundary vertices from smoothing.

## Rest Source

Select the source for reference vertex positions that defines the undeformed state.

## Original Coordinates

Use the original input vertex positions. This relies on the original mesh having the same number of vertices as the input, modified mesh.

## Bind Coordinates

Optionally you may bind the modifier to a specific state. This is required when there are constructive modifiers such as Subdivision Surface or Mirror in the stack before this modifier.

## Smooth Laplacian

The Smooth Laplacian modifier tries to reduce noise on a mesh's surface with minimal changes to its shape. It can also exaggerate the shape using a negative Factor.

## Repeat

Repeat the smoothing operation multiple times. Each repetition causes the flow curvature of the mesh to be

recalculated again, and as a result it removes more noise with every new iteration using a small Factor  $< 1.0$ .

With a value of 0, no smoothing is done.

## Axis

Enable deforming in single axis directions. The axis are in world space.

## Lambda Factor

Controls the amount of displacement of every vertex along the flow curvature.

## Lambda Border

Border edges must be controlled separately. Border edges are controlled by the lambda border value.

## Preserve Volume

The smoothing process can shrink the volume. Preserve Volume tries to prevent that.

## Normalized

Normalize the results dependent on face sizes. When disabled, geometry spikes may occur.

## Vertex Group

Limit the modifier effect to a vertex group.

## Invert

Inverts the influence of the vertex group.

---

## Surface Deform

The Surface Deform modifier allows an arbitrary mesh surface to control the deformation of another object.

A use case is to use a cloth simulation of a low poly mesh to drive the motion of your final mesh.

The target mesh:

- Must not contain edges with more than two faces.
- Must not contain concave faces.
- Must not contain overlapping vertices (doubles).
- Must not contain faces with co-linear edges.

Note! The meshes are bound in global coordinates. But later transformations on the objects are ignored. This means that one can freely transform the target or modified object after binding, without affecting the modified object. The modified mesh will only pick up changes to the target object's mesh itself.

Note! The more a mesh surface differs from the target mesh surface, the more likely it will show undesirable artifacts. So it is recommended to have reasonably well matching meshes to get a good bind.

## **Workflow**

Create a cloth simulation at your low poly object.

Create the high poly version.

Add the Surface Deform modifier.

Choose the object with the cloth simulation as the target.

Click at the Bind button to make the deformation real.

The object with the modifier applied will now deform, following the vertice motion of the source object.

## **Target**

The object with the cloth deform animation.

## **Interpolation Falloff**

How much a vertex bound to one face of the target will be affected by the surrounding faces. This essentially controls how smooth the deformations are. This setting becomes unavailable after binding.

Note! Lower values result in smoother deformations, but may also introduce artifacts.

## **Strength**

The overall amount of influence the modifier has on deforming the mesh.

## **Vertex Group**

Limit the influence to a vertex group.

## ***Invert***

Inverts the influence of the selected vertex group.

## **Sparse Bind**

Requires to choose a vertex group. Only record binding data for vertices matching the vertex group at the time of bind.

## **Bind**

Bind the current state of the modified mesh to the current state of the target mesh. Any later change in the target mesh will deform the source mesh then. Bind is required to make the modifier work.

## **Unbind**

Unbind the source mesh from the target mesh.

## Warp

The Warp modifier warps parts of a mesh to a new location by using two target objects. The deformation goes into the direction from the first target object to the second target object. This target objects can be of any type. Empty, Lamp, Camera, etc. For demonstration purposes two spheres are used.

### Object From

The object to define the origin transformation of the warp.

### Object To

The object to define the destination transformation of the warp.

### Preserve Volume

Enables volume preservation when rotating one of the transforms.

### Strength

Sets how strong the effect is.

### Vertex Group

Limit the modifier to a vertex group.

### *Invert*

Inverts the influence of the selected vertex group.

### Falloff

#### *Falloff Type*

The falloff type. How the strength of the warp changes as it goes from the center of the transform to the Radius value.

#### *Radius*

The distance from the transforms that can be warped by the transform handles.

### Texture

A texture allows you to control how the vertices are affected by the modifier.

### *Usage*

Add a texture.

Head over to the Texture tab.

In the texture tab either load an existing texture. Or create one. A procedural Noise texture for example.

## Texture Prop

### Texture browser

A list of the available textures

### Texture Edit Box

The name of the currently active texture. Allows to rename the texture too.

### Fake User

Keep this data even when it has no user in the scene.

### Add Texture

Add a new texture.

### Remove

Removes the texture. Note that the texture is still in the browser list.

### Change Context

Jump to texture tab and show the texture.

### Coordinates

What texture coordinate system to use.

## Wave

The Wave modifier adds a ripple-like shape to an object's geometry. The shape can be animated by playing the animation.

This modifier works with meshes, lattices, curves, surfaces and texts.

Important! All the values are in local object space. They must be multiplied with the corresponding Scale values of the object to get the real dimensions.

To obtain a nice wave effect similar to sea waves and close to a sinusoidal wave, make the distance between following ripples and the ripple width equal. That is, the Narrowness value must be equal to 2 / Width. E.g. for Width to be 1, set Narrow to 2.

## Motion

The wave effect deforms vertices/control points in the Z direction. The initial start point is the object origin. The direction is then in X or Y direction. With both activated you get a circle shape.

## Cyclic

Repeats the waves.

When you want to have more circles at frame 1 already, then use a negative Offset in the Time subpanel.

## Along Normals

For meshes only. Displaces the mesh along the surface normals (instead of the object's Z axis).

## X/Y/Z

Restrict displacement along normals to the selected local axes.

## Falloff

Controls how fast the waves fade out as they travel away from the starting point.

## Height

The height or amplitude of the ripple.

## Width

Distance between the waves. If the pulses are too near to each other, the wave may not reach the zero Z position. In this case the whole wave gets lowered so that the minimum is zero, and the maximum is lower than the expected amplitude.

## Narrowness

The actual width of each pulse.

The higher the value the narrower the pulse. The actual width of the area for a single is given by 4 / Narrowness.

## Vertex Group

Limit the effect of the modifier to a vertex group.

## ***Invert***

Inverts the influence of the selected vertex group.

## **Start Position**

### ***Object***

Use the origin of another object as the starting point.

### ***Start Position X/Y***

Coordinates of the center of the waves, in object's local space.

## **Time**

Settings to control the animation.

### ***Offset***

Time offset in frames. The frame at which the wave begins (if Speed is positive), or ends (if Speed is negative). Use a negative frame number to prime and pre-start the waves.

### ***Life***

Duration of animation in frames. With a value of zero the animation loops forever.

### ***Damping***

An additional number of frames in which the wave slowly damps from the Height value to zero after Life is reached. The dampening occurs for all the ripples and begins in the first frame after the Life is over. Ripples disappear over Damping frames.

### ***Speed***

The speed per frame, of the ripple.

## **Texture subtab**

A texture allows you to control how the vertices are affected by the modifier.

## **Usage**

Add a texture.

Head over to the Texture tab.

In the texture tab either load an existing texture. Or create one. A procedural Noise texture for example.

## Texture Prop

## Texture browser

A list of the available textures

## Texture Edit Box

The name of the currently active texture. Allows to rename the texture too.

## Fake User

Keep this data even when it has no user in the scene.

## Add Texture

Add a new texture.

## Remove

Removes the texture. Note that the texture is still in the browser list.

## Change Context

Jump to texture tab and show the texture.

---

## Coordinates

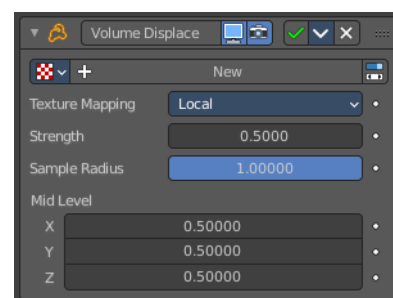

What texture coordinate system to use.

---

## Volume Displace

The Volume Displace modifier displaces existing volume grids by a 3D texture. It uses the RGB color channels of the texture to displace the volume into the X, Y and Z direction.

## Texture Prop

The texture to use for the displacement of the voxels. For a three dimensional displacement colored textures should be used. Greyscale images just displaces into one direction. Colored images into all three directions.

## Texture Browser

A list of the available textures in the scene. Textures can be added in the Texture tab in the Properties Editor.

## Edit Box

The name of the texture. Here you can also rename the texture.

## Change Context

Jump to the Texture tab to load a texture.

## Unlink

Removes the currently active texture.

## File selector menu

### New

Creates a new texture slot. It is blank. You first need to load a texture, which can be done in the Texture tab in the Properties Editor.

### Duplicate

Not active in this context.

### Unlink

Removes the currently active texture.

### Add Fake User

With this button you assign a fake user to this selected world.

Data, like worlds, that is not longer linked to anything else gets removed when you save and reload a scene. Bforartists has the concept of fake users to go around this behavior. An image with a fake user is in fact linked to something. And so it is not lost when you save and reload the scene.

### User

The number of users that uses this data. Data with a user number of 0 will be removed with closing Bforartists.

---

## Texture Mapping

What space to use to map the texture onto the object.

## **Strength**

Controls how far voxels are displaced.

## **Sample Radius**

Smaller values result in better performance, but might cut off the volume outside.

## **Mid Level X Y Z**

This should be modified if the texture offsets the entire volume in one direction and you want to center it again. For performance reasons, the displaced volume should stay close to its original position.

## Mesh - Physics modifiers

### Available content

#### Mesh object

Contains various physics modifiers. Some of these are editable from the Physics Tab in the Properties editor.

- Cloth
- Collision
- Dynamic Paint
- Explode
- Fluid
- Ocean
- Particle Instance
- Particle System
- Soft Body

#### Curve + Text object

- Soft Body

#### Lattice Object

- Soft Body

## Cloth

The cloth modifier gets added into the modifier stack when you add a cloth physics in the Physics tab. It enables cloth simulation for the mesh.

All the cloth settings and adjustments happens in the Physics tab. The cloth modifier has no further settings.

## Collision

The collision modifier gets added into the modifier stack when you add a collision physics in the Physics tab. It enables collision for the mesh.

All the collision settings and adjustments happens in the Physics tab. The collision modifier has no further settings.

## Dynamic Paint

The dynamic paint modifier gets added into the modifier stack when you add a dynamic paint physics in the Physics tab. It enables dynamic painting. Which turns objects into paintable canvasses to modify vertex colors or displacement. Like footsteps in snow.

All the collision settings and adjustments happens in the Physics tab. The dynamic paint modifier has no further settings.

## Explode

The Explode modifier gets added into the modifier stack when you add a Quick Explode quick effect, together with a particle system. It splits the object apart, and uses the split parts as particles for an explosion like particle animation.

The modifier requires particles to work. The particles effect controls how the explosion looks like. And the explode modifier must come after the particles modifier.

The Explode modifier has some further settings. But all the particles settings and adjustments happens in the Physics tab.

## Particle UV

The UV map to change with particle age. The U value of the coordinates in that UV map will be overwritten with the age of the particle attached to the matching mesh face. In proportion, from 0 for not yet born particles, to 1 for dead ones.

The V value is set to a constant 0.5 value.

This allows to make the color of a fragment (face) vary during its 'explosion' phase, by using a texture with a gradient of colors along its U axis.

## Alive / Dead / Unborn

### Alive

Show faces when their attached particles are alive.

### Dead

Show faces when their attached particles are dead.

### Unborn

Show faces when their attached particles are unborn.

## Cut Edges

Split the mesh in pieces based on location of emitted particles, instead of using existing faces. This will produce a splitting that appears more random.

## Size

Scale each face using the size of its attached particle, once that particle is alive.

## Vertex Group

Limit the modifier effect to a vertex group.

## ***Invert***

Inverts the influence of the selected vertex group.

## ***Protect***

Clean vertex group edges.

Depending on the weights assigned to that vertex group. A value of 1 completely protect those faces from being affected by the Explode modifier. A value of 0 fully applies the modifier to the faces.

## **Refresh**

Refresh data in the Explode modifier.

---

## **Fluid**

The fluid modifier gets added into the modifier stack when you add a fluid physics in the Physics tab. It enables fluid simulations.

All the settings and adjustments happens in the Physics tab. The fluid modifier has no further settings.

#

## Ocean

The Ocean modifier is a tool to simulate and generate a deforming ocean surface. It is intended to simulate deep ocean waves and foam.

By default, the simulator only generates displacement data, since it takes the least amount of work and gives the fastest feedback. Additional simulation data can be generated for rendering as well.

## Geometry

### **Generate**

Creates a tiled mesh grid. The existing mesh object is replaced by the ocean grid. The generated mesh comes with UV mapping.

### **Displace**

The ocean modifier displaces the existing mesh.

### **Repeat X, Repeat Y**

How often the grid is tiled in X and Y directions. The UV's gets repeated.

## Resolution

The resolution of the internal 2D grids generated by the simulation.

The internal grids are powers of two of the resolution value. So a resolution value of 16 will create simulation data of size 256×256. The higher the resolution, the more details will be produced, but the slower it will be to calculate.

Note! When using the Generate modifier geometry option, this resolution value also determines the resolution of the generated mesh surface, equal to the resolution of the internal simulation data.

## Time

The time at which the ocean surface is being evaluated. To make an animated ocean, you will need to animate this value by adding keyframes. The speed that the time value is changing will determine the speed of the wave animation.

## Depth

The constant depth of the ocean floor under the simulated area. Lower values simulate shallower waters by producing higher frequency details and smaller waves.

## Size

A simple scaling factor that does not affect the height of the waves or behavior of the simulation.

## Spatial Size

The width of the ocean surface area being simulated, in meters. This also determines the size of the generated mesh, or the displaced area. Of course, you can scale the object with the Ocean modifier in Object Mode to tweak the apparent size in your scene.

## Random Seed

A different seed will produce a different simulation result.

## Generate Normals

Simulates additional normal map data.

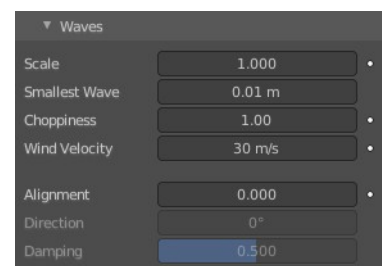

When mapped to Normals, this can be used by the Ocean texture as a bump map. And enables generating normal map image sequences when baking.

## Waves

### Scale

An overall scale control for the amplitude of the waves. It approximates the height or depth of the waves above or below zero.

Rather than just scaling the ocean object in Z, it scales all aspects of the simulation, displacement in X and Y, and corresponding foam and normals too.

### Smallest Wave

A minimum limit for the size of generated waves. Acts similarly to a low-pass filter, removing higher frequency wave detail.

### Choppiness

The choppiness of the wave peaks. With a choppiness of 0, the ocean surface is only displaced up and down in the Z direction, but with higher choppiness, the waves are also displaced laterally in X and Y, to create sharper wave peaks.

### Wind Velocity

Wind speed in meters/second. With a low velocity, waves are restricted to smaller surface waves.

### Alignment

The directionality of the wave shapes due to wind. At a value of 0, the wind and waves are randomly, uniformly oriented.

With higher Alignment values, the wind is blowing in a more constant direction, making the waves appear more compressed and aligned to a single direction.

## ***Direction***

The direction in degrees that the waves are aligned to. X axis is used as reference.

## ***Damping***

The amount that inter-reflected waves are damped out. This has the effect of making the wave motion more directional, and not just the wave shape.

With a Damping of 0.0, waves are reflected off each other in every direction, with a Damping of 1.0, these inter-reflected waves are damped out, leaving only waves traveling in the direction of the wind.

## **Foam**

Simulate extra foam data.

### ***Data Layer***

Type in a name. This name defines a vertex data layer which is used by the Ocean Modifier to store a foam map as vertex colors. This name is then used to access this vertex data layer by an Attribute node in the ocean material.

Note that creating the full working ocean material is an own chapter, which cannot be covered here.

## ***Coverage***

The amount of foam covering the waves. Negative values will reduce the amount of foam, and leave only the topmost peaks. Positive values will add to it.

## ***Spray***

### ***Data Layer***

Type in a name. This name defines a vertex data layer which is used by the Ocean Modifier to store a spray direction map as vertex colors. This name is then used to access this vertex data layer by an Attribute node in the ocean material.

## **Invert**

Inverts the spray direction map.

## Spectrum

### *Spectrum*

What wave spectrum model to use. Wave spectra are used to describe how energy moves through the waves at different frequencies. Energy travels through waves differently depending on the depth of the water and the wind speed.

### **Turbulent Ocean**

Use for turbulent seas with foam (Phillips).

### **Established Ocean**

Use for a large area, established ocean where the ocean would extend for miles with wind blowing for days allowing the waves to reach a point of equilibrium (Pierson-Moskowitz method).

### **Established Ocean (Sharp Peaks)**

Similar to regular Established Ocean however, waves will continue to grow with time creating sharper peaks (JONSWAP and Pierson-Moskowitz method). An extra parameter is used to define the sharpness of these peaks.

### **Shallow Water**

Use for shallow water with depths less than about 10 meters which makes it great for small lakes and ponds without heavy wind (JONSWAP and TMA – Texel-Marsen-Arsloe methods).

## Bake

The data for the ocean modifier can be baked to files in a given directory.

When a simulation is baked, the simulator engine is completely bypassed, and the modifier/texture retrieves all information from the baked files. Baked files are faster, allows rendering in external renderers, and enables more advanced foam maps.

The created images are stored in exr format. And can be opened and modified in any graphics software that is able to handle the format.

### ***Bake Ocean***

Bake an image sequence of ocean data.

### ***Cache Path***

Folder to store the baked EXR files in. The sequences will be in the form `disp_####.exr`, `normal_####.exr`, and `foam_####.exr`, where `####` is the four digit frame number. If the cache path folder does not exist, it will be created.

### ***Frame Start, End***

Frames of the simulation to bake (inclusive). The start and end frames of the bake are repeated when accessing frames outside of the baked range.

## Foam Fade

How much the foam accumulates over time. This feature is for baked ocean only.

## Particle Instance

Adds a copy of the mesh to the particle positions of a particle system. This happens relative to the object origin.

To use this modifier you must have at least one other object that has a Particles System attached.

Because of how the Particle Instance modifier influences the underlying particle systems on other objects, some of the effects generated by the modifier can look and act different. This depends on the underlying settings of the particle systems it is associated with.

## Object

Add the target object with the particle system.

## Particle System

The particle system from the target Object to use.

## Create Instances

Instance settings.

## Regular

The modifier will use the regular (parents) particles to duplicate the mesh of the modified object.

## Children

The modifier will use the children particles to duplicate the mesh of the modified object.

## Size

Scale the instanced copies of the mesh by the particle size attribute. When disabled, all the copies appear the same size as the origin.

## Show

Particle display settings.

## Unborn

Use the unborn particles to duplicate the mesh to.

## Alive

Use the alive particles to duplicate the mesh to.

## Dead

Use the dead particles to duplicate the mesh to.

## Amount

Allows you to randomly skip particles to adjust the amount of instances.

Warning! The random algorithm used currently only ensures that relative amount to be respected statistically. The actual amount of instances generated will differ from the theoretical one, depending on the Seed value of the target particle system (and the Offset value described below, too).

That deviation is not significant with high number of particles, but it will be highly noticeable with low numbers (e.g. with 100 particles in the target system, and an Amount value of 0.1, it can generate either up to 15 or 5 instances, instead of the 10 expected).

## Offset

A relative offset in the range of particles used for instantiation. Allows you to avoid overlapping of the used particles, when the same particle system is used in multiple modifier instances.

Tip! If you want to fully avoid overlaps, your Offset value must be at least as high as your Amount value.

## Coordinate Space

What coordinate system to use for the target object. World space or Local space.

With World space the locations of the copies of the modified mesh will depend on the location of the modified object and of the target object.

With Local space the locations of the copies of the modified mesh will depend only on the location of the modified object.

## Axis

Which axis of the modified object to use as pole axis to apply the rotation from the instantiated particles. Only one axis can be chosen.

## Create Along Paths

By default, the instances are placed depending on the particles position in the current frame. By enabling Create Along Paths, the instance of the modified object follows deforms its shape along the particle path (or the hair strand). This allows you to select the position along the particles path regardless of the current frame.

Tip! You can adjust the path of particles on the Render panel of the Particle System tab by adjusting the Path visualization type

Note! When the type is not Hair or Keyed Physics, the particle system must be baked.

Note! When you use Strands you must also have Dead activated in the Show settings. Since they die immediately.

### **Position**

What percentage of the path that the instance fills. Or the position on the path if the Keep Shape option is enabled.

### **Random**

Adds randomness to the Position value of each instance.

### **Rotation**

Specifies the rotation around the path.

### **Random**

Adds randomness to the Rotation value of each instance.

### **Keep Shape**

Enabling this prevents the instance from being deformed, and places it on the path according to the Position value.

## **Layers**

Select vertex color layers. These layers will be filled with colors based on the particles information. And can be used in a shader to add variance to a material.

You can create vertex color layers in the Object Data properties in the Vertex Colors panel.

### **Index**

A vertex color layer for values based on the particles index.

### **Value**

A vertex color layer for random per-particle values.

## Particle System

The Particle System modifier gets added into the modifier stack when you add a particle system in the Particles tab. It enables particle simulation at the object.

All the particle settings and adjustments happens in the Particles tab. The Particle System modifier has no further settings.

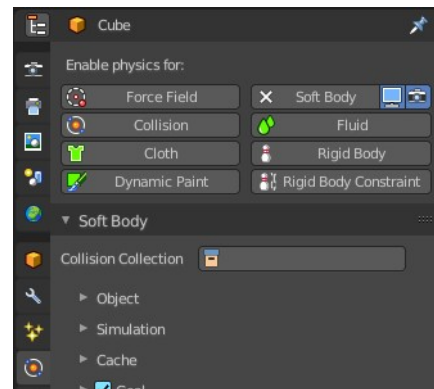

## Soft body

The Soft body modifier gets added into the modifier stack when you add a Soft Body physics in the Physics tab. It enables Soft Body simulation for the mesh.

All the Soft body settings and adjustments happens in the Physics tab. The Soft body modifier has no further settings.

## Grease Pencil - Modify modifiers

### Texture Mapping

The Texture Mapping Modifier changes the strokes texture UV position.

### Mode

The texture transformation will be applied to the stroke/fill or stroke UVs.

### Stroke

### Stroke Fit Method

The texture fitting method.

#### *Constant Length*

The texture keep a consistent length along the strokes.

#### *Stroke Length*

The texture is normalized to fit the stroke length.

### UV Offset

Moves the texture along the strokes.

### Rotation

Rotates the points of the strokes. Note that the Rotation option is limited to a range of -90 to 90 degrees.

## Scale

Factor for the texture scale.

---

## Fill

### Fill Rotation

Sets the texture angle.

### Offset X / Y

Moves the texture origin in x and/or y direction

### Scale

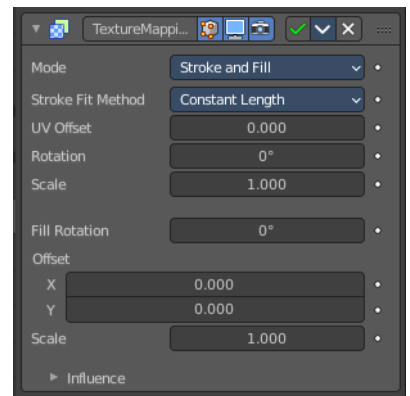

Factor for the texture scale.

---

## Stroke and Fill

See both single chapters above.

## Influence Subpanel

### Influence

#### Layer

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

#### Invert

Inverts the influence.

#### Pass

The layer pass index.

#### Invert

Inverts the influence.

## **Material**

Restricts the effect only to one layer or to any layers that share the same material index. Click to pick the layer that you want to use.

## **Invert**

Inverts the influence.

## **Pass**

The layer pass index.

## **Invert**

Inverts the influence.

## **Vertex Group**

Restricts the effect only to one vertex group. Click to choose the vertex group.

## **Invert**

Inverts the influence.

---

## **Time Offset Modifier**

Grease Pencil object only. The Time Offset Modifier offsets the position of Grease Pencil keyframes.

## **Mode**

### **Regular**

Offsets keyframes in default animation playback direction (left to right).

### **Reverse**

Offsets keyframes in inverse animation playback direction (right to left).

### **Fixed Frame**

Keep the selected frame fixed and do not change over time.

### **Ping Pong**

Plays forwards then backwards in a loop.

## **Chain**

List of chained animation elements.

## **Frame Offset**

Number of frames to offset the original keyframes.

## **Scale**

Evaluation time (in seconds).

## **Keep Loop**

Moves end frame to the animation start to keep animation in a loop.

---

The following just shows with Mode Chain:

## **Segment List**

Here you can define animation segments that you want to chain.

## **Add /Remove Segment**

Add or remove a segment.

## **Move Up / Down**

Move a segment up or down in the list.

## **Mode**

The mode of the segment.

## **Regular**

Offsets keyframes in default animation playback direction (left to right).

## **Reverse**

Offsets keyframes in inverse animation playback direction (right to left).

## **Ping Pong**

Plays forwards then backwards in a loop.

## **Frame Start**

The start frame of the segment.

## **End**

The end frame of the segment.

## **Repeat**

How often to repeat the segment.

---

## **Custom Range subpanel**

Use a custom range of frames.

### **Frame Start / End**

Sets the range start and end frames.

## **Influence subpanel**

### **Layer**

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### **Invert**

Inverts the influence.

### **Pass**

The layer pass index.

### **Invert**

Inverts the influence.

---

## **Vertex Weight Angle**

This modifier sets the weights of a vertex group based of the angle of the geometry.

Warning! This modifier does implicit clamping of weight values in the standard (0.0 to 1.0) range. All values below 0.0 will be set to 0.0, and all values above 1.0 will be set to 1.0.

Note! You can view the modified weights in Weight Paint Mode. This also implies that you will have to disable the Vertex Weight Proximity modifier if you want to see the original weights of the vertex group you are editing.

### **Vertex Group**

Which vertex group to use.

## Angle

Distance angle to 0.0 weight. Tip! Lowest can be set above Highest to reverse the mapping.

## Axis

Which axis to use.

## Space

In which space to calculate. Local or Global.

## Minimum

Minimum value for vertex weight.

## Multiply Weights

Multiply the calculated weights with the existing values of the vertex group.

---

## Influence Subpanel

### Influence

#### *Layer*

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

#### **Invert**

Inverts the influence.

#### **Pass**

The layer pass index.

#### **Invert**

Inverts the influence.

#### **Material**

Restricts the effect only to one layer or to any layers that share the same material index. Click to pick the layer that you want to use.

#### **Invert**

Inverts the influence.

## **Pass**

The layer pass index.

## **Invert**

Inverts the influence.

## **Vertex Group**

Restricts the effect only to one vertex group. Click to choose the vertex group.

## **Invert**

Inverts the influence.

---

## **Vertex Weight Proximity**

This modifier sets the weights of the given vertex group, based on the distance between the object (or its vertices), and another target object (or its geometry).

**Warning1** This modifier does implicit clamping of weight values in the standard (0.0 to 1.0) range. All values below 0.0 will be set to 0.0, and all values above 1.0 will be set to 1.0.

**Note!** You can view the modified weights in Weight Paint Mode. This also implies that you will have to disable the Vertex Weight Proximity modifier if you want to see the original weights of the vertex group you are editing.

## **Vertex Group**

The vertex group to affect.

## **Target Object**

The object from which to compute distances.

## **Lowest**

Distance mapping to 0.0 weight. Tip! Lowest can be set above Highest to reverse the mapping.

## **Highest**

Distance mapping to 1.0 weight.

## **Minimum**

Minimum value for vertex weight.

## Multiply Weights

Multiply the calculated weights with the existing values of the vertex group.

---

## Influence Subpanel

### Influence

#### **Layer**

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

#### **Invert**

Inverts the influence.

#### **Pass**

The layer pass index.

#### **Invert**

Inverts the influence.

#### **Material**

Restricts the effect only to one layer or to any layers that share the same material index. Click to pick the layer that you want to use.

#### **Invert**

Inverts the influence.

#### **Pass**

The layer pass index.

#### **Invert**

Inverts the influence.

#### **Vertex Group**

Restricts the effect only to one vertex group. Click to choose the vertex group.

#### **Invert**

Inverts the influence.

## Grease Pencil - Generate modifiers

Some of the modifiers are just available for specific object types.

Left grease pencil object, right a mesh object.

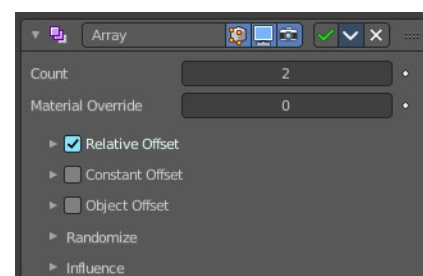

### Array

The Array modifier creates an array of copies of the base object. Each copy can offset from the previous one in any of a number of possible ways. Vertices in adjacent copies can be merged if they are nearby, allowing smooth Subdivision Surface frameworks to be generated.

This modifier can be useful when combined with tillable meshes for quickly developing large scenes. It is also useful for creating complex repetitive shapes.

Multiple Array modifiers may be active for an object at the same time. This allows to create complex three-dimensional constructs.

Hint for Offset Calculation. The transformation applied from one copy to the next is calculated as the sum of the three different components (Relative, Constant and Object), each of which can be enabled/disabled independently of the others. This allows, for example, a relative offset of (1.0, 0.0, 0.0) and a constant offset of (0.1, 0.0, 0.0), giving an array of objects neatly spaced along the X axis with a constant 0.1 unit between them, whatever the original object's size.

### Count

Number of Items

### Material Override

Index of the material used for generated strokes. A value of 0 uses the original material.

### Relative Offset subpanel

#### Factor X/Y/Z

Adds a translation equal to the object's bounding box size along each axis to

the offset, multiplied by a scaling factor. X, Y and Z scaling factors can be specified.

## Constant Offset subpanel

### *Distance X/Y/Z*

Adds a constant translation component to the duplicate object's offset. X, Y and Z constant components can be specified.

## Object Offset subpanel

Adds a transformation taken from a chosen object relative to the current object to the offset.

### *Object*

Choose an object.

## Randomize

Randomize the transform values.

### *Offset*

Randomize the offset values.

### *Rotation*

Randomize the rotation values.

### *Scale*

Randomize the scale values.

### **Uniform Scale**

Use uniform scaling.

### *Seed*

The random seed value.

## Influence subpanel

### *Layer*

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### **Inverse Layers**

Inverts the influence.

## Pass

The layer pass index.

### Inverse Pass

Inverts the influence.

## Material

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

### Invert Materials

Inverts the influence.

## Pass

The material pass index.

### Inverse Pass

Inverts the influence.

## Build

The Build modifier lets the strokes of the grease pencil object appear or disappear over time when you play the animation.

## Mode

How many strokes are animated at the same time.

### Sequential mode

Strokes appear or disappear one after the other.

## Transition

How the strokes are animated. The items should be self explaining.

## Timing

How to calculate the timing of the frames.

### **Natural Drawing Speed**

Use recorded speed multiplied by a factor.

### **Speed Factor**

Multiply recorded drawing speed by a factor.

### **Maximum Gap**

The maximum gap between strokes in seconds.

### **Number of Frames**

Set a fixed number of frames for all build animations.

### **Frames**

Maximum number of frames that the build effect can run.

### **Delay**

Number of frames to delay before the modifier has any effect.

### **Percentage Factor**

Set a manual percentage to build.

### **Factor**

How much the stroke is visible.

### **Object**

Pick an object as the starting position.

## **Concurrent Mode**

All strokes appear or disappear at once.

### **Transition**

How the strokes are animated.

### **Grow**

Grow over the animation time.

### **Shrink**

Shrink over the animation time.

## **Vanish**

Vanish over the animation time.

## **Timing**

What method to use to build animations. Number of frames, or percentage.

## **Number of frames**

## **Time Alignment**

When strokes should start to appear or disappear.

### **Align Start**

All strokes appears at the same time.

### **Align End**

All strokes disappears at the same time.

## **Frames**

Maximum number of frames that the build effect can run.

## **Delay**

Number of frames after each GP keyframe before the modifier has any effect.

## **Percentage Factor**

## **Time Alignment**

When strokes should start to appear or disappear.

### **Align Start**

All strokes appears at the same time.

### **Align End**

All strokes disappears at the same time.

## **Factor**

How much the stroke is visible.

## **Object**

Pick an object as the starting position.

## Additive

Builds only new strokes. Assumes additive painting.

## Timing

What method to use to build animations.

### Natural Drawing Speed

#### Speed Factor

Multiply the recording speed by a factor.

#### Maximum Gap

The maximum gap between strokes in seconds.

### Number of frames

## Time Alignment

When strokes should start to appear or disappear.

### Align Start

All strokes appears at the same time.

### Align End

All strokes disappears at the same time.

## Frames

Maximum number of frames that the build effect can run.

## Delay

Number of frames after each GP keyframe before the modifier has any effect.

### Percentage Factor

## Time Alignment

When strokes should start to appear or disappear.

### Align Start

All strokes appears at the same time.

### ***Align End***

All strokes disappears at the same time.

### **Factor**

How much the stroke is visible.

### **Start delay**

Number of frames after each GP keyframe before the modifier has any effect.

### **Frames**

Maximum number of frames that the build effect can run.

### **Object**

Pick an object as the starting position.

---

## **Custom Range**

Only modify strokes that lies in the specified time frame.

### ***Start***

The first frame of the range.

### ***End***

The last frame of the range.

## **Fade subpanel**

Fade out strokes instead of cutting them off.

### ***Factor***

The factor for how much the stroke is fading out.

### ***Thickness***

How much strength fading applies on top of stroke thickness.

### ***Opacity***

How much strength fading applies on top of stroke opacity.

### ***Weight Output***

Limit the fade to a vertex group.

## **Influence subpanel**

### ***Layer***

Restricts the effect only to one layer or to any layers that share the same pass

index. Click to pick the layer that you want to use.

## Inverse Layers

Inverts the influence.

## Pass

The layer pass index.

## Inverse Pass

Inverts the influence.

## Dot Dash

Turns a grease pencil stroke into a dotted line.

## Offset

The offset into each stroke before the dot creation starts.

## Segment list

Manage the single segments of the dotted dash. Segments gets repeated as they appear in the list. Means when you just have one segment in the list, then this shape will be repeated. When you have two, then the first will be displayed, then the second, then the first, and so on. Every segment can have its own settings. Which are managed below.

## Add Segment

Add a new dash segment.

## Remove Segment

Remove the dash segment.

## Move Dash Segment up or down

Moves the selected dash segment up or down in the list.

## Search element

By clicking at the triangle button you reveal a search field with which you can search through the list.

## Edit Box

Type in the search term and hit enter.

## Invert

Inverts the search term.

## Sort by name

Sorts the list alphabetically.

## Reverse

Inverts the list.

## Dash

The number of points (vertices) from the original stroke to include in this segment.

## Gap

The number of points (vertices) skipped after this segment.

## Radius

The radius of the segment. Maximum is 1 of the original stroke.

## Opacity

The visibility of this segment.

## Material Index

What material to use.

## Cyclic

Enable cyclic on individual stroke dashes.

## Influence subpanel

### *Layer*

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### *Inverse Layers*

Inverts the influence.

### *Pass*

The layer pass index.

### *Inverse Pass*

Inverts the influence.

### *Material*

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

## **Invert Materials**

Inverts the influence.

## **Pass**

The material pass index.

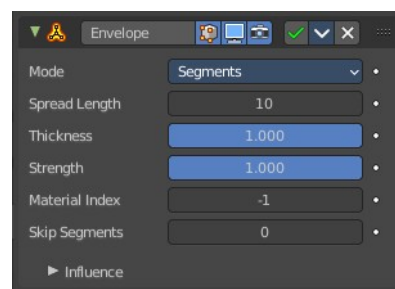

## **Inverse Pass**

Inverts the influence.

---

## **Envelope**

Generates an envelope shape that connects all points in this envelope.

## **Mode**

### ***Deform***

Deform the stroke to best match the envelope shape.

### ***Segments***

Add segments to create the envelope. Keep the original stroke.

### ***Fills***

Add Fill segments to create the envelope. This method does not keep the original stroke.

## **Spread Length**

The number of points to skip to create straight segments.

## **Thickness**

Thickness multiplier for the thickness of the new stroke.

## **Strength**

Strength multiplier for the strength of the new stroke.

## **Material Index**

The material index of the material that is used.

## **Skip Segments**

Define a number of segments to skip to reduce the complexity.

## Influence subpanel

### **Layer**

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### **Inverse Layers**

Inverts the influence.

### **Pass**

The layer pass index.

### **Inverse Pass**

Inverts the influence.

### **Material**

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

### **Invert Materials**

Inverts the influence.

### **Pass**

The material pass index.

### **Inverse Pass**

Inverts the influence.

### **Vertex Group**

Assign a vertex group to modulate the deform.

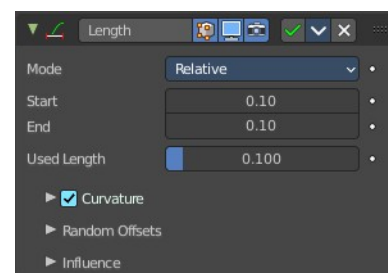

### **Inverse Pass**

Inverts the influence.

## Length

The Length Modifier extends or shortens the original strokes length.

## Mode

Defines the mode to use for the length calculation. Relative to the length of the grease pencil stroke, or absolute in geometry space.

## Factor Start/End

Length difference for each stroke.

## Used Length

What position of the stroke is used for the calculation of the extension.

## Curvature subpanel

Follow the curvature of the stroke.

### *Point Density*

Multiplied by Start/End for the total added point count.

### *Segment Influence*

How much the length of the individual segments should influence the final computed curvature.

### *Filter Angle*

Ignore points of the stroke that derivate from their neighbours by more than this angle.

### *Invert*

Invert the curvature of the stroke's extension.

## Random Offset subpanel

Randomization for the start / end lengths.

### *Random offset Start*

Size of random length added to the start of each stroke.

### *Random offset End*

Size of random length added to the end of each stroke.

### *Random Noise Offset*

Smoothly offset the random value of each stroke.

### *Seed*

The random seed value.

## Randomize subpanel

Use random values over time.

## Step

Number of frames before recalculate random values again.

## Influence subpanel

### Layer

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### Inverse Layers

Inverts the influence.

### Pass

The layer pass index.

### Inverse Pass

Inverts the influence.

### Material

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

### Invert Materials

Inverts the influence.

### Pass

The material pass index.

### Inverse Pass

Inverts the influence.

## Line Art

The Line Art modifier generates stylized line art from the scene or selected source collection or objects.

Note that due to lack of global cache at the moment, each Line Art modifier will run the entire occlusion calculation for itself. So if you have multiple line art modifiers to select different parts of the scene (to apply different styles, etc.), the evaluation will take much longer. There are plans to remedy this in the future, but this is a known limitation for now.

This modifier requires to have a **ACTIVE** camera in the scene, since the outline is created from this active camera. And the outline is created from exact this view of the camera. So better switch to camera view to check if the view fits.

The active camera has the active orange triangle above the widget. You can also see the active camera in the Scene properties.

## Source Type

What type of geometry source should line art be generated from.

### Collection

#### Collection

The collection where you want to apply the line art to.

#### Invert

Inverts the selection of collections.

#### Layer

Grease Pencil layer that is assigned to the generated strokes.

#### Material

Grease pencil material assigned to the generated strokes.

#### Line Thickness

The thickness of the line.

#### Opacity

The opacity of the line.

### Object

#### Object

The object where you want to apply the line art to.

## Layer

Grease Pencil layer that is assigned to the generated strokes.

## Material

Grease pencil material assigned to the generated strokes.

## Line Thickness

The thickness of the line.

## Opacity

The opacity of the line.

---

## Scene

Applies the line art grease pencil strokes to the whole scene.

## Layer

Grease Pencil layer that is assigned to the generated strokes.

## Material

Grease pencil material assigned to the generated strokes.

## Line Thickness

The thickness of the line.

## Opacity

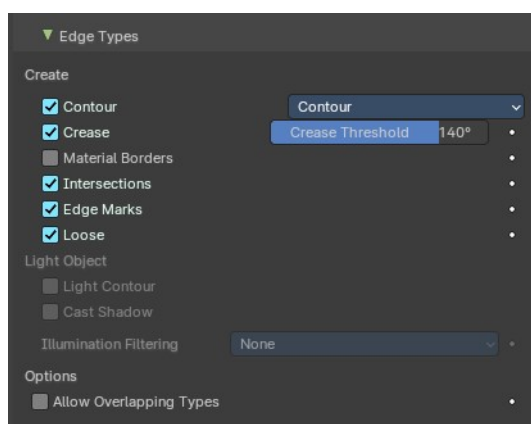

The opacity of the line.

---

## Edge types subpanel

Which kind of edges to influence.

## Create

### Use Contour

Use a contour.

## ***Silhouette Filtering***

What kind of contour to use.

## **Use Crease**

Generate strokes from crease edges.

## ***Crease Threshold***

Angles smaller than this value will be treated as creases.

## **Crease**

Influence crease edges. The angle what edges are treated as creases can be adjusted in the edit box.

## **Material Borders**

Generate strokes from borders between materials.

## **Intersections**

Generate strokes from intersections.

## **Edge Marks**

Generate strokes from edge marks.

## **Loose**

Generate strokes from loose geometry.

## ***Light Object***

### **Light Contour**

You need to pick a light object in the Light Reference panel. Generate light shadow separation lines from a referenced light object.

### **Cast Shadow**

You need to pick a light object in the Light Reference panel. The line casts shadow.

### **Illumination filtering**

You need to pick a light object in the Light Reference panel. How to thread the shadow region filtering. The names should be self explaining.

## ***Options***

### **Allow Overlapping Types**

Allow an edge to have multiple overlapping types.

---

## **Light Reference subpanel**

This panel allows you to add a light object as a source for line art.

## ***Light Object***

Pick the light source.

## ***Shadow Camera Size***

Represents the orthographic scale of an ortho camera. It calculates the area to cover.

## ***Near***

The near clip plane of the shadow camera.

## ***Far***

The far clip plane of the shadow camera.

---

## **Geometry Processing subpanel**

## ***Custom Camera***

Allows to pick a different camera than the active scene camera for line art rendering.

## ***Overlapping Edges as Contour***

This option allows overlapping edges (e.g. from an edge split modifier or imported geometry where two edges occupy the exact same space) to be drawn as contour. Enabling this option will slow down the calculation slightly but it will handle edge overlapping cases without erroneous occlusion results.

## ***Instanced Objects***

This option enables particles and other instanced objects to be loaded for line art calculation. There will be performance impact when there are a large amount of instanced objects in the scene.

## ***Clipping Boundaries***

When enabled, line art will generate clipping lines as contour type at the place where near or far clipping planes cut the model. Otherwise there will be no lines.

## ***Crease on Smooth***

Allow crease edges to show inside smooth surfaces.

## ***Crease on Sharp***

Allow crease to show on sharp edges.

## ***Force Back Face Culling***

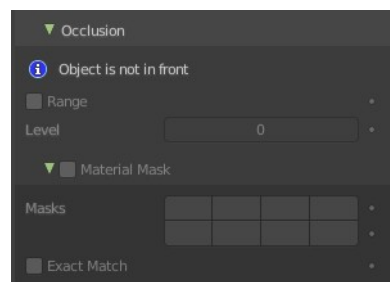

Remove all backfaces to speed up calculation.

## Occlusion Subpanel

### Range

If enabled, the modifier will select lines that have an occlusion level between start and end values.

If not enabled just a single Level value slider shows.

### Material Mask subpanel

Use material masks to filter out occluded strokes. You need to have a range level higher than 0.

### Masks

Choose up to eight mask bits for the masking.

### Exact match

Require matching all material masks instead of just one.

## Intersection subpanel

### Collection Masks

Choose up to eight mask bits for masking.

### Exact match

Require matching all intersections instead of just one.

## Face Mask Filtering subpanel

Filter Feature Lines using Freestlye Face Masks.

### Invert

Invert face mask filtering.

### Boundaries

Filter feature lines based on face mask boundaries.

### Keep Contour

Preserve contour lines while filtering.

## Chain

### ***Intersection with Contour***

Allows intersection lines to be chained together with contour lines.

### ***All Lines***

Enabling this option will cause all lines to have the type of contour and to be chained together.

### ***Loose Edges***

Allow loose edges to be chained together.

### ***Loose As Contour***

Loose edges will have contour type.

### ***Preserve Details***

Keep the zig-zag noise in initial channing.

### ***Geometry Space***

Use Geometry distance for chaining instead of image space.

### ***Image Threshold***

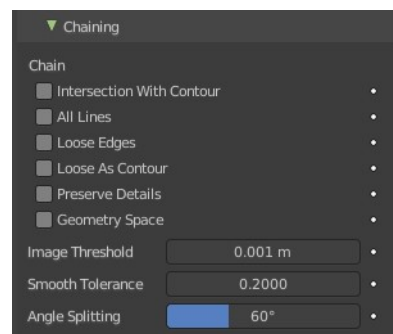

Segments with an image distance smaller than this value will be chained together.

### ***Smooth tolerance***

Strength of smoothing applied on jagged chains.

### ***Angle Splitting***

The angle in screen space below which a stroke is split into two.

## Vertex Weight Transfer subpanel

### ***Filter Source***

If source mesh has vertex groups whose name starts with this string, then the vertex weight info will be transferred into weight groups in Grease Pencil strokes.

### ***Invert Vertex Group***

Inverts the selection.

### ***Match Output***

Transfer the filtered object vertex weights into Grease Pencil weight groups with the same names as the filtered ones.

## Target

If Match Output is off, then a target vertex group has to be specified. If there are multiple weight groups copied into target, then the highest weight value is copied into it.

## Composition

### Overscan

A margin to prevent an abrupt end of the stroke at the edge of the image.

### Image boundary trimming

Trim all edges right at the boundary of image (including overscan region)

### Depth Offset

Move strokes slightly towards the camera to avoid clipping.

### Towards custom camera

Offset strokes towards selected camera instead of the active camera.

## Bake subpanel

### Bake Line Art / Bake Line Art (All)

Bakes Line Art strokes for active Grease Pencil object within the start, end frame range in scene.

Bake Line Art (All) bakes all Grease Pencil objects that contains at least one Line Art modifier. After baking, baked Line Art modifier will be deactivated automatically.

### Clear Baked Line Art / Clear Baked Line Art (All)

Clears baked line art frames within the scene frame range for active Grease Pencil object.

Clear Baked Line Art (All) applies the same operation for all Grease Pencil objects that contains at least one Line Art modifier.

## Mirror

The Mirror modifier for the Grease Pencil Object works in Object mode. It mirrors the object along its local X, Y and/or Z axes, across the Object Origin.

It can also use another object as the mirror center, then use that object's local axes instead of its own.

### Object

Define an object to mirror at its origin instead of mirroring along the grease pencil origin.

You can animate it to move the mirror axis.

## Influence

### Layer

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### Invert

Inverts the influence.

### Pass

The layer pass index.

### Invert

Inverts the influence.

### Material

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

### Invert

Inverts the influence.

### Pass

The material pass index.

### Invert

Inverts the influence.

## Multiple Strokes

Adds multiple parallel copies of the stroke around the original stroke.

### Duplicates

The number of additional strokes.

### Distance

Distance between the original and the duplicate strokes.

### Offset

Control the offset position (inner or outer) for duplicate strokes.

## Fade

Fade out duplicate strokes, using their opacity or thickness.

## Center

Control the initial position for the fading.

## Thickness

Fade influence on strokes thickness.

## Opacity

Fade influence on strokes opacity.

## Influence

### Layer

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### Invert

Inverts the influence.

### Pass

The layer pass index.

### Invert

Inverts the influence.

### Material

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

### Invert

Inverts the influence.

### Pass

The material pass index.

### Invert

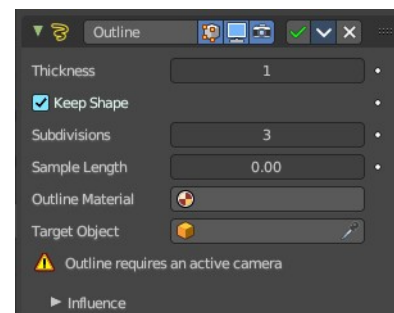

Inverts the influence.

## Outline

Draws an outline around the grease pencil stroke.

This modifier requires to have a **ACTIVE** camera in the scene, since the outline is created from this active camera. And the outline is created from exact this view of the camera. So better switch to camera view to check if the view fits. You will get a warning in the modifier when the active camera is missing.

The active camera has the active orange triangle above the widget. You can also see the active camera in the Scene properties.

## Thickness

The thickness of the outline.

## Keep Shape

Try to keep global shape.

## Subdivisions

Subdivisions of the outline grease pencil stroke.

## Sample Length

The distance between the vertices.

## Outline material

Material used for the outline strokes. If no material is chosen then the material from the parent stroke is used.

## Target object

A target object to define the stroke start.

## Influence

### Layer

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### Invert

Inverts the influence.

### Pass

The layer pass index.

### Invert

Inverts the influence.

## Simplify

The Simplify modifier allows you to reduce the amount of points in the strokes. It tries to reduce points while maintaining the lines shape.

### Mode

How to reduce points in the strokes.

### Fixed

Deletes alternated points in the strokes, except the start and end points.

### Adaptive

Uses the RDP algorithm (Ramer-Douglas-Peucker algorithm) for points deletion. The algorithm try to obtain a similar line shape with fewer points.

### Sample

Recreates the stroke geometry with a predefined length between points.

### Merge

Simplifies the strokes by merging points that are closer than a specified distance to each other.

### Iterations

Number of times to repeat the procedure.

## Influence

### Layer

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### Invert

Inverts the influence.

### Pass

The layer pass index.

### Invert

Inverts the influence.

### Material

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

### Invert

Inverts the influence.

### Pass

The material pass index.

### Invert

Inverts the influence.

## Subdivide

The Subdivide modifier subdivide the strokes by inserting points between other points to the lines.

### Subdivision Type

#### Catmull-Clark

Subdivides and smooths the surfaces.

#### Simple

Only subdivides the surfaces, without any smoothing.

## Subdivisions

Number of subdivisions.

## Influence

### *Layer*

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### **Invert**

Inverts the influence.

### *Pass*

The layer pass index.

### **Invert**

Inverts the influence.

### *Material*

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

### **Invert**

Inverts the influence.

### *Pass*

The material pass index.

### **Invert**

Inverts the influence.

## Deform modifiers

### Armature

An armature system allows to deform objects accurately by posing bones. The Armature modifier contains the armature settings at the mesh end.

This modifier gets created automatically when you parent a grease pencil to an armature.

The armature modifier has two extra entries in the dropdown menu in the header.

### Apply as Shape Key

Apply the modifier as a new shapekey to the mesh, and remove the armature modifier.

### Save as Shape Key

Apply the modifier as a new shapekey to the mesh, but keep the armature modifier.

## Object

The name of the armature object used by this modifier.

## Vertex Group

A vertex group of the object, which weights will be used to determine the influence of this modifier's results when mixing it with the results from other Armature ones.

This is only of use when having at least two of these modifiers on the same object, with Multi Modifier activated.

## Invert

Inverts the influence set by the vertex group.

## Bind to

### Vertex Groups

Meshes and lattices only. Use Vertex groups for deforming the mesh. A bone named "forearm", will only affect the vertices in the "forearm" vertex group. The influence of one bone on a given vertex is controlled by the weight of this vertex in the relevant group.

The vertex groups are located in the Object Data Properties in the Properties editor.

### Bone Envelopes

Use the Bone envelopes to deform vertices or control points near them, defined by each bone's envelope radius and distance.

When envelopes are disabled, Blender uses the set of existing vertex group names to determine which bones influences what mesh part.

Bone envelopes display can be turned on in the Viewport Display panel in the Object Data properties tab in the Properties Editor. Display as ...

And can be adjusted in the Transform panel in the sidebar of the 3D View, in Edit mode.

## Hook

The Hook modifier is used to deform a mesh, curve or lattice by another object. When you move this hook object, then it pulls vertices or control points with it.

Assigning the hook object to specific vertices of the target object is done in Edit mode. The modifier shows a set of buttons then.

This modifier is automatically created when you add a Hook from the Hooks menu in the Edge menu in edit mode.

Some settings just exists in Edit mode.

Warning! The Hook Modifier stores vertex indices from the original mesh to determine what to affect. Modifiers that generate geometry, like Subdivision Surface, should always be put after the Hook modifier in the stack. Otherwise, the generated geometry can't be affected by the hook's influence.

## Object

The name of the object to hook vertices to.

## Vertex Group

Allows you to define the influence per vertex.

## Invert

Inverts the influence of the selected vertex group.

## Strength

Adjust this hooks influence on the vertices.

## Reset

In Edit mode. Recalculate and clear the offset transform of the hook.

## Recenter

In Edit mode. Set the hook center to the 3D cursor position.

## Select

In Edit mode. Select the vertices affected by this hook.

## Assign

In Edit mode. Assigns selected vertices to this hook.

## Falloff

### Type

This can be used to adjust the kind of influence curve that the hook has on the mesh. You can also define a custom curve to get a much higher level of control.

### Radius

The size of the hooks influence.

### Uniform Falloff

Compensate non uniform scale, and use a uniform falloff.

## Influence

### Layer

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### Invert

Inverts the influence.

### Pass

The layer pass index.

### Invert

Inverts the influence.

## **Material**

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

## **Invert**

Inverts the influence.

## **Pass**

The material pass index.

## **Invert**

Inverts the influence.

---

## **Lattice**

The Lattice modifier deforms the base object by the shape of a Lattice object. It can be used at meshes, curves, surfaces, text, lattices and even particles.

A Lattice modifier with valid settings can be added by selecting the object, holding down shift, select the target lattice object, and then choose Lattice Deform in the Parent menu.

Note! When you want to use a lattice to deform particles, then you need to place the Lattice modifier after the Particle System modifier.

## **Object**

The Lattice object that deforms the base object.

## **Vertex Group**

Limit the modifier's effect to a vertex group of the base mesh.

## **Invert**

Inverts the influence of the selected vertex group.

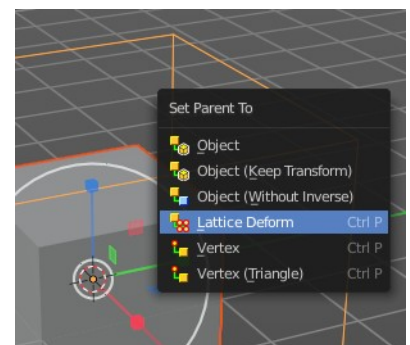

## **Strength**

A factor to control blending between original and deformed vertex positions.

## **Influence**

## **Layer**

Restricts the effect only to one layer or to any layers that share the same pass

index. Click to pick the layer that you want to use.

### **Invert**

Inverts the influence.

### **Pass**

The layer pass index.

### **Invert**

Inverts the influence.

### **Material**

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

### **Invert**

Inverts the influence.

### **Pass**

The material pass index.

### **Invert**

Inverts the influence.

---

## **Noise**

The Noise Modifier adds noise to make the grease pencil line unstable and noisy.

### **Position**

Strength of the noise effect over the point location.

### **Strength**

Strength of the noise effect over the point strength (opacity).

### **Thickness**

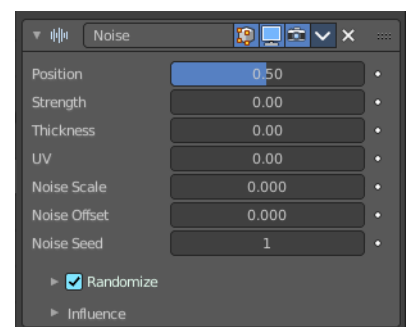

Strength of the noise effect over the point thickness.

### **UV**

Strength of the noise effect over the point UV rotation.

### **Noise Scale**

Control the noise frequency scale.

## Noise Offset

Offset the noise along the stroke.

## Noise Seed

Add a random seed.

## Randomize

Use a random value over time.

## Step

Number of frames before using a new random value.

## Influence

### Layer

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### Invert

Inverts the influence.

### Pass

The layer pass index.

### Invert

Inverts the influence.

### Material

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

### Invert

Inverts the influence.

### Pass

The material pass index.

### Invert

Inverts the influence.

### Vertex Group

Limit the influence to a vertex group.

## Invert

Inverts the influence.

## Custom Curve

Use a custom curve to define the noise along the strokes.

## Navigation elements

The navigation elements at the top are described from left to right.

## Zoom in and out

The two buttons with the magnifying glass at it zooms in and out in the curve window.

## Tools

Tools is a menu where you can find some curve related tools.

### Reset View

Resets the curve windows zoom.

### Vector Handle

Set handle type to Vector.

### Auto Handle

Set handle type to Auto.

### Auto Clamped Handle

Set handle type to Auto Clamped.

### Extend Horizontal

Extend the curve points horizontal before the first curve point and after the last curve point.

### Extend Vertical

Extend the curve points vertical before the first curve point and after the last curve point.

### Reset Curve

Resets the curve to the initial shape.

## Use Clipping

Clipping options. Set up clipping for the stroke.

## Delete Points

Deletes selected curve points.

## Curve window

Tweak and adjust the falloff curve by clicking at a curve point and dragging it around.

Double click adds a new point.

Holding down ctrl activates temporary snapping.

Holding down shift enables slower movement, which allows more accurate setting.

## X / Y

The position of the currently selected curve point.

## Offset

The Offset Modifier changes the strokes location, rotation or scale, starting from the object origin.

### General Subpanel

#### Location X, Y, Z

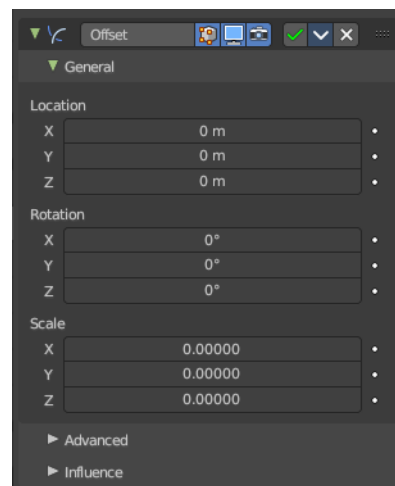

Sets strokes location offset from its object origin.

#### Rotation X, Y, Z

Sets strokes rotation.

#### Scale X, Y, Z

Sets strokes scale.

### Advanced Subpanel

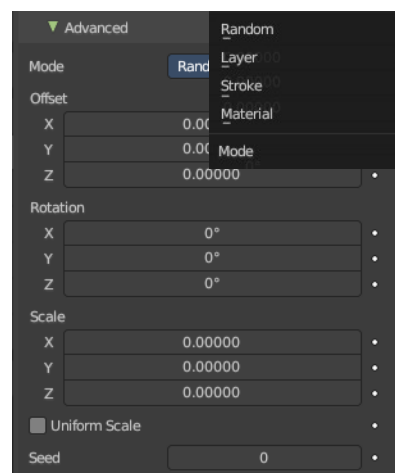

#### Mode

#### Random

Randomize Stroke Offset.

#### Layer

Offset Layers by the same factor.

### **Stroke**

Offset stroke by the same factor based on stroke draw order.

### **Material**

Offset materials by the same factor.

### **Offset**

Randomize the offset in x y and z axis.

### **Rotation**

Randomize the rotation in x y and z angle.

### **Scale**

Randomize the size in x y and z axis.

### **Uniform Scale**

Mode random. Use the same random seed for each scale axis for a uniform scale.

### **Seed**

Mode Random. The random seed for the uniform scale.

### **Layer Step**

Mode Seed. Number of elements that will be grouped.

### **Layer Offset**

Mode Seed. Offset Starting Point.

### **Stroke Step**

Mode Stroke. Number of elements that will be grouped.

### **Stroke Offset**

Mode Stroke. Offset Starting Point.

### **Material Step**

Mode Material. Number of elements that will be grouped.

### **Material Offset**

Mode Material. Offset Starting Point.

---

## Influence subpanel

### **Layer**

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### **Invert**

Inverts the influence.

### **Pass**

The layer pass index.

### **Invert**

Inverts the influence.

### **Material**

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

### **Invert**

Inverts the influence.

### **Pass**

The material pass index.

### **Invert**

Inverts the influence.

### **Vertex Group**

Limit the influence to a vertex group.

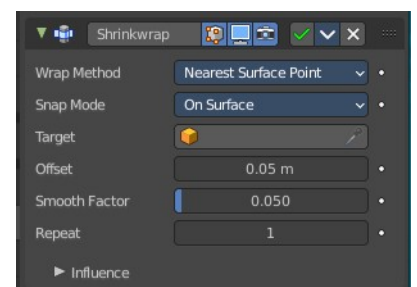

### **Invert**

Inverts the influence.

---

## Shrinkwrap

Shrinks the geometry to the surface of another object.

## Wrap Method

The method to determine the nearest point on the target's surface for each vertex of the object.

### **Nearest Surface Point + Target Normal Project**

Nearest Surface Point selects the nearest point at the surface. Additionally, Target Normal Project tries to match the interpolated normals of the surface.

### **Snap Mode**

How the vertex snaps to the surface. The methods should be self explaining.

### **Target**

The target mesh to shrink to.

## Project

Projects all vertices along a chosen axis until they hit the surface of the target object.

Vertices that never hits the surface are not calculated.

### **Snap Mode**

How the vertex snaps to the surface. The methods should be self explaining.

### **Limit**

A distance limit between original vertex and surface. If the distance is larger than this limit vertex would not be projected onto the surface.

### **Subdivision Levels**

This applies a (temporary) Catmull-Clark subdivision to the modified object's geometry, before computing the wrap.

### **Axis**

Along which local axis of the modified object the projection is done. These options can be combined with each other, yielding a "median axis" of projection. If none are selected, the normal direction is used.

### **Negative/Positive**

This allows you to select the allowed direction(s) of the shrink along the selected axis. If both options are enabled, both ways are evaluated and the closest hit is selected.

### **Face Cull**

Allows you to prevent any projection over the "front side" or the "back side" of the target's faces. The "side" of

a face is determined by its normal.

### ***Invert Cull***

When projecting in the negative direction then invert culling.

You need to have negative ticked and face cull either front or back to set this property active.

### **Target**

The target mesh to shrink to.

### **Auxiliary Target**

An additional object to project to.

### ***Nearest Vertex***

### **Target**

The target mesh to shrink to.

### **Offset**

An offset distance to keep to the target surface.

### **Smooth factor**

Amount of smoothing to apply

### **Repeat**

Number of steps to apply smooth.

### **Vertex Group**

Restrict the affected vertices to a vertex group.

### ***Invert***

Inverts the influence of the selected vertex group.

### **Influence subpanel**

#### ***Layer***

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

#### **Invert**

Inverts the influence.

## ***Pass***

The layer pass index.

## **Invert**

Inverts the influence.

## ***Material***

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

## **Invert**

Inverts the influence.

## ***Pass***

The material pass index.

## **Invert**

Inverts the influence.

## ***Vertex Group***

Limit the influence to a vertex group.

## **Invert**

Inverts the influence.

---

## **Smooth**

The Smooth modifier smoothens a stroke.

## **Mode**

What elements to affect.

## ***Position***

Affects the position of the point.

## ***Strength***

Affects the color strength of the point

## ***Thickness***

Affects the thickness of the point.

## ***UV***

Affects the uv rotation factor of the point.

## **Factor**

The smoothing amount. Higher values will increase the effect. Values outside expected range (above 1.0 or below 0.0) will distort the mesh.

## **Repeat**

The number of smoothing iterations.

## **Influence**

### ***Layer***

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

### **Invert**

Inverts the influence.

### ***Pass***

The layer pass index.

### **Invert**

Inverts the influence.

### ***Material***

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

### **Invert**

Inverts the influence.

### ***Pass***

The material pass index.

### **Invert**

Inverts the influence.

### ***Vertex Group***

Limit the influence to a vertex group.

### **Invert**

Inverts the influence.

## Custom Curve

Use a custom curve to define the noise along the strokes.

### Navigation elements

The navigation elements at the top are described from left to right.

### Zoom in and out

The two buttons with the magnifying glass at it zooms in and out in the curve window.

## Thickness

The Thickness Modifier change the stroke points thickness.

### Uniform Thickness

When enabled, makes the thickness equal for the entire strokes.

### Thickness Factor

Value to add or subtract to the actual points thickness.

### Weighted

Use weight to modulate effect.

### Influence

#### Layer

Restricts the effect only to one layer or to any layers that share the same pass index. Click to pick the layer that you want to use.

#### Invert

Inverts the influence.

#### Pass

The layer pass index.

#### Invert

Inverts the influence.

## **Material**

Restricts the effect only to material that share the same material or pass index. Click to pick the material that you want to use.

## **Invert**

Inverts the influence.

## **Pass**

The material pass index.

## **Invert**

Inverts the influence.

## **Vertex Group**

Limit the influence to a vertex group.

## **Invert**

Inverts the influence.

## **Custom Curve**

Use a custom curve to define the noise along the strokes.

## **Navigation elements**

The navigation elements at the top are described from left to right.

## **Zoom in and out**

The two buttons with the magnifying glass at it zooms in and out in the curve window.

---

## **Tools**

Tools is a menu where you can find some curve related tools.

### **Reset View**

Resets the curve windows zoom.

### **Vector Handle**

Set handle type to Vector.

### **Auto Handle**

Set handle type to Auto.

### **Auto Clamped Handle**

Set handle type to Auto Clamped.

### **Extend Horizontal**

Extend the curve points horizontal before the first curve point and after the last curve point.

### **Extend Vertical**

Extend the curve points vertical before the first curve point and after the last curve point.

### **Reset Curve**

Resets the curve to the initial shape.

---

### **Use Clipping**

Clipping options. Set up clipping for the stroke.

### **Delete Points**

Deletes selected curve points.

---

### **Curve window**

Tweak and adjust the falloff curve by clicking at a curve point and dragging it around.

Double click adds a new point.

Holding down ctrl activates temporary snapping.

Holding down shift enables slower movement, which allows more accurate setting.

### **X / Y**

The position of the currently selected curve point.

## 25.8 Editors - Properties Editor - Modifiers Tab

Modifiers are automatic operations that affects the geometry of objects in a non destructive way. You can, for example ,subdivide a mesh object dynamically where the base geometry stays intact when in edit mode.

Modifiers can also be applied to the object and “frozen”.

In this case the change is destructive.

Modifiers gets added in a modifier stack. Choose a modifier from the list, and re-arrange the modifiers per your needs. Modifiers can build on top of each other and can be reordered. Sometimes the order of operations is important.

## Object types with modifiers

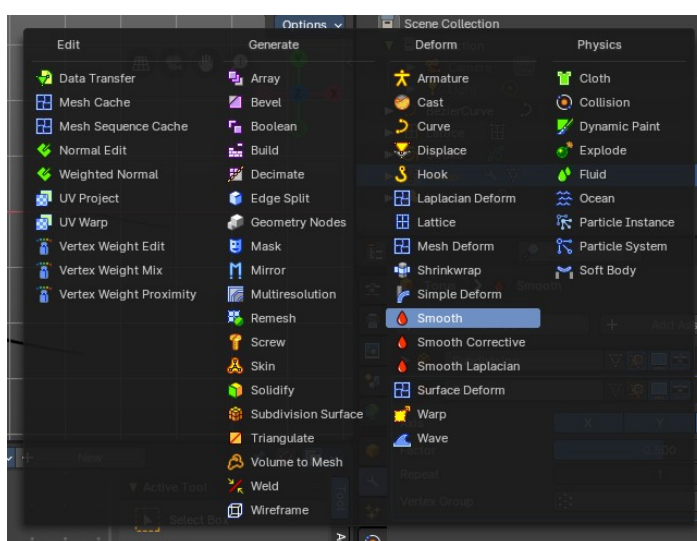

There are two general types of objects where you can use modifiers. Mesh objects and Curve objects. The Grease Pencil object is a special object in this regards and has some exclusive modifiers that the other object types does not have. The Grease Pencil object is under the hood also a curve object.

Each object types shows a different set of modifiers. Some modifiers have the same name, but shows different settings for different object types.

### Mesh object

These show modifiers divided into four categories: Edit, Generate, Deform and Physics.

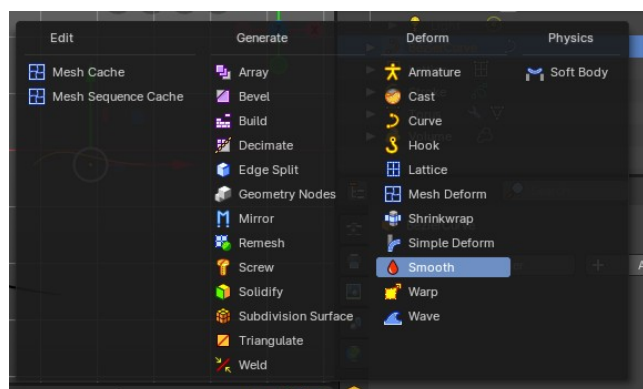

You can also use Geometry Nodes Asset Modifiers.

### Curve + Text Object

These show modifiers divided into four categories: Edit, Generate, Deform and Physics.

You can also use Geometry Nodes Asset Modifiers.

### Volume Object

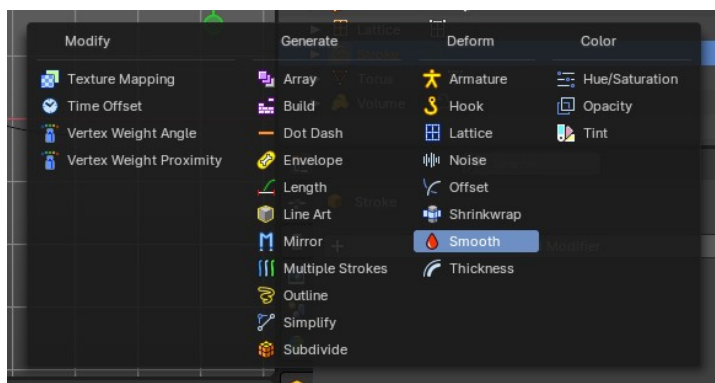

These show modifiers divided into two categories: Generate and Deform.

You can also use Geometry Nodes Asset Modifiers.

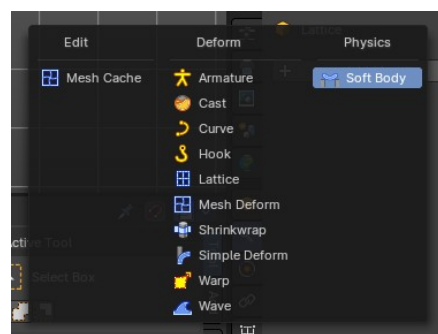

## Grease Pencil Object

These show modifiers divided into four categories: Edit, Generate, Deform and Color.

## Lattice Object

These show modifiers divided into three categories: Edit, Deform and Physics.

## Modifier types

There are several types of modifiers:

### Geometry Nodes

This allows you to insert a Geometry Nodes modifier.

### Modify

Change the shape of an object, without altering its topology. But not directly, but by some other data like vertex groups.

### Generate

Constructive/destructive tools that will affect the whole Topology of the mesh. They can change the general appearance of the object, or add new geometry to it.

### Deform

Change the shape of an object, without altering its topology.

### Simulate

Those represent physics simulations. In most cases, they are automatically added to the modifiers stack

whenever a Particle System or Physics simulation is enabled. Their only role is to define the position in the modifier stack from which is taken the base data for the simulation they represent. As such, they typically have no attributes, and are controlled by settings exposed in separate sections of the Properties.

## **Color**

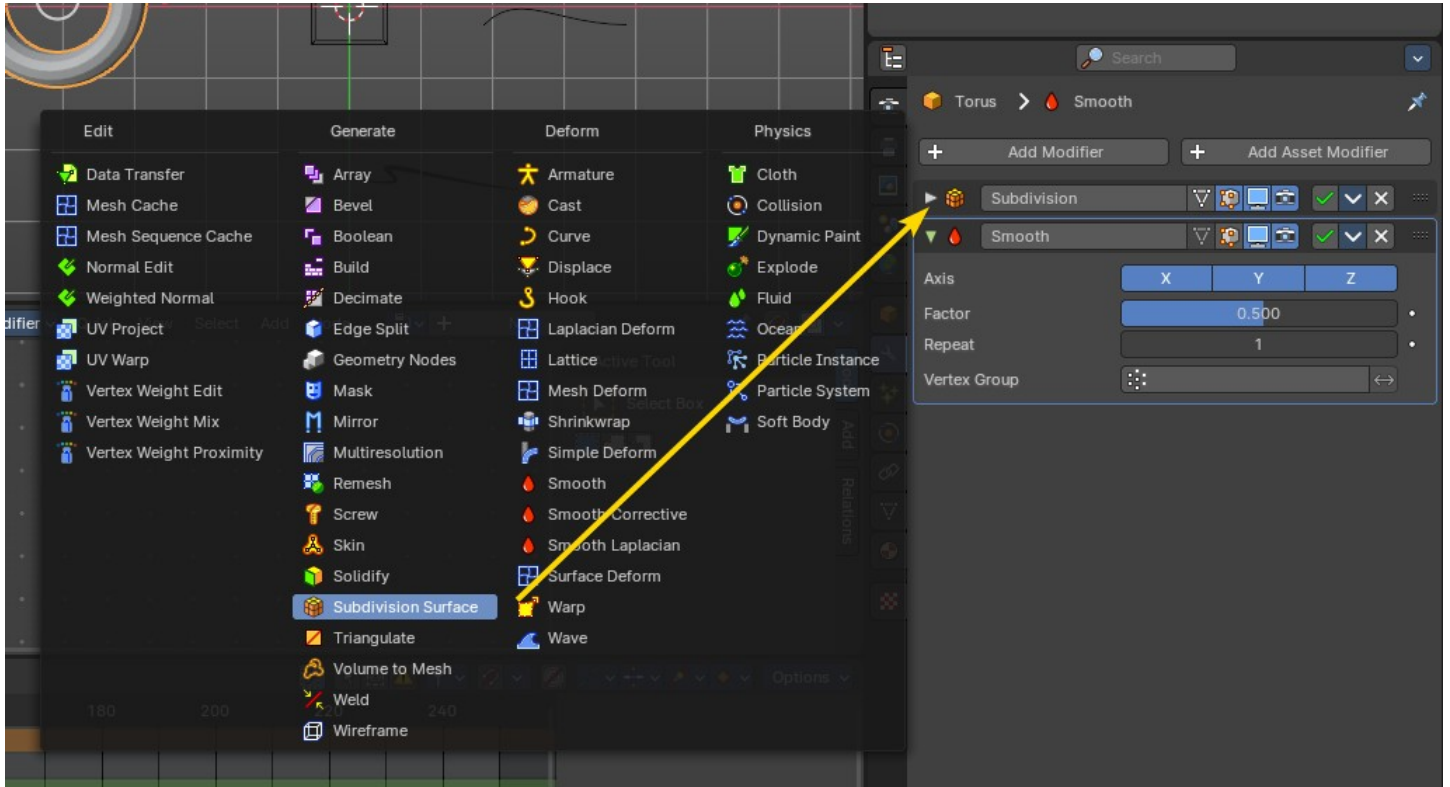

Just for the grease pencil object. Adds some modifiers to adjust the color.

## **Hair**

Mesh Object. Add Hair Curve Modifiers.

# General functionality

## Add Modifier

To add a modifier to a selection of objects, simply open the add menu, and choose the type of modifier that you want to add.

This will add the modifier to the list on your selection.

For some modifiers you will also find menu items in the 3D view. The Quick effect Fluid will for example add a fluid and liquid particle system modifier.

This menu entries exists to simplify the workflow. This menu entries are described in other chapters.

**Note:** To add modifiers will generally apply to all selected objects, unless you press and hold ALT and click on the operators. When removing and applying modifiers, they will generally apply to all selected objects, unless you press and hold ALT and click on the operators.

## Header elements

You might want to disable a modifier temporarily. Or just see the effect in the final rendering. This can be adjusted in the header. The header is what you see when you collapse the modifier panel.

Note that not all modifiers have the same header content. Fluid modifiers for example doesn't even have a remove button. They get removed by removing the fluid simulation in the physics tab.

Elements are explained from left to right.

## Collapse panel

The whole modifier panel can be collapsed. Click at the arrow button up left in the header.

## Modifier Icon

This icon shows the type of the modifier. And has no further functionality.

## Modifier Name

The name of the modifier. You can rename modifiers by clicking into the edit field and change the text.

## On Cage

Adjust edit cage to modifier result. With this option the geometry will be viewed at the position they will be after the modifier is calculated. Important for the mirror modifier for example.

## Edit Mode

Display the modifier result in edit mode.

## Realtime

Display the modifier in the viewport.

## Render

Display the modifier in the rendered result.

---

## Apply

This will apply the modifier, and it destructively change the mesh.

**Note:** *If multiple objects have the same modifier with the same name, they will be applied to the selection. If you want to apply to only the Active object, press and hold ALT then click on the operator.*

---

## Header menu

### **Apply as Shapekey**

Armature modifier. Applies the current pose as a shape key, and removes the modifier.

### **Save as Shapekey**

Armature modifier. Applies the current pose as a shape key, and keeps the modifier.

### **Duplicate**

Duplicates the modifier, and places the duplicate below the current modifier.

### **Copy to Selected**

Copies the modifier to the selected object. First select the object where you want to paste the modifier to. Then select the object with the modifier with holding down shift so that both objects are selected. Now use Copy to Selected. And the modifier will copy over to the first object. Works also with multiple objects.

### **Move to first**

Move the modifier to the first position in the stack.

### **Move to last**

Move the modifier to the last position in the stack.

### **Move to Nodes**

Hair modifier. Moves the modifier to nodes instead.

### **Show Node Groups**

Hair modifier. Shows the node groups prop in the modifier

## Remove

Removes the modifier from the stack on all selected objects.

**Note:** *If multiple objects have the same modifier with the same name, they will be removed from the selection. If you want to remove from only the Active object, press and hold ALT then click on the operator.*

## Pin to Last

Keep the modifier at the end of the list. You can pin multiple modifiers at the end of the stack. The order of the pinned modifiers is set by the order that you pin the modifiers.

## Change Context

Some modifiers cannot be removed from the modifiers stack directly. Like fluid modifiers. You need to remove the fluid simulation instead, in the physics tab. With the change context button you jump to the required tab where you can now remove the simulation.

## Reorder

You can have more than one modifier in the list. And sometimes the order of the modifiers is very important.

Grab the handler at the right and drag the modifier to the position where you want it to have.

## Animate Property

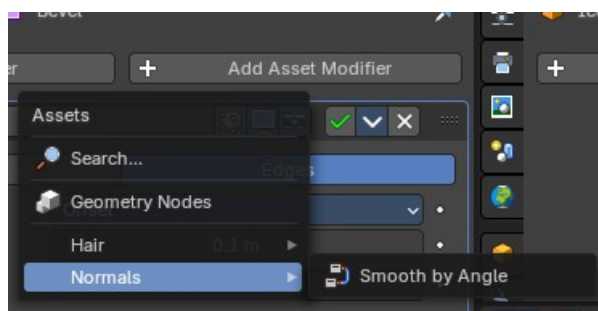

Some of the properties can be animated. Click at the animate property button at the right to add a keyframe.

## Add Asset Modifier

Add a modifier nodegroup into the modifier stack. This will list and create all Geometry Node group assets assigned to the Modifier property. If they are not assigned to a category in the Asset Browser, they will list as “unassigned”.

For more information, please check out the chapter **Editors - Properties Editor - Modifiers Properties Tab - Add Modifier menus**

## Properties Editor

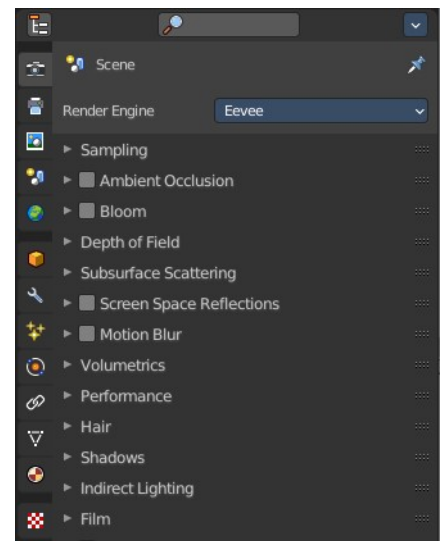

The Properties Editor is the core to manage the data in Bforartists. It is used to edit data and properties for the Active Scene and the Active Object. It contains Scene and Object related settings and properties. It contains all the tool settings for the current active tool. And it contains global settings and properties, like Render settings. Materials, Particle settings. etc.

The Properties editor is divided into several tabs. And the tabs are divided into several panels. The tabs buttons can be found asides.

Various content just appears when you are in the right context. Means when you have a specific object type selected, are in a specific mode, etc.

### Hotkey functionality

You can scroll through the tabs by holding down ctrl and using the scroll wheel.

## Slider snapping

Snapping also works at sliders. Hover with the mouse over the slider, start to slide, and holding down **Ctrl** will snap the sliders in incremental steps.

When it's a default value between 0 and 1 then it usually snaps in 0.1 steps. When it's a default value over 1 then it usually snaps in steps of 10.

## Header and Tabs

The header contains a button to switch to Outliner and back. And it contains a search and a context pin.

### Search

Allows you to search for specific terms. All not matching content is greyed out. When the matching term is in one of the closed panels, then this panel will open up.

### Options

#### Sync with Outliner

Adjust if properties editor is in sync with the outliner. It can make sense to turn off sync for performance reasons.

#### On

Always sync outliner with properties editor.

#### Off

Never sync outliner with properties editor.

#### Auto

Sync outliner with properties editor when they share an edge with each other.

### Context pin

The header can also contain a pin icon in some areas. This pin icon allows you to collapse the tabs to just the tabs that are available for the currently selected kind of object type.

### Editortype Menu

You can display a Editortype Menu in the header. This menu allows you to switch to another editor type. Note that this menu

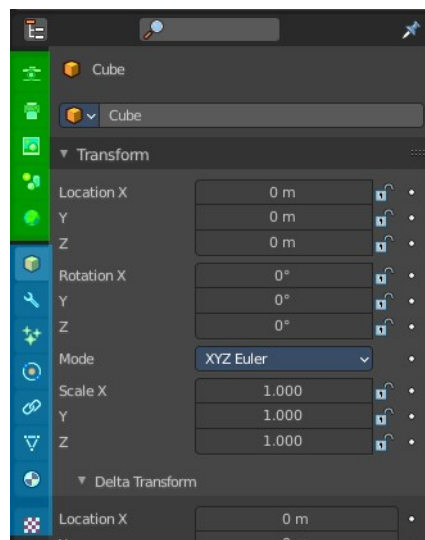

is hidden by default. You can reveal it in the right click menu of the header area.

## Navigation Tabs

The navigation tabs to navigate in the Properties Editor are vertically aligned besides the editor.

It is divided into two sections. Globals Section. Green. and Object Data section. Blue.

## Tabs position

The tabs can be displayed at the left or at the right side. Either click right in the empty space of the tab area. This will bring up the Context menu where you can flip the whole tabs menu bar to the right or to the left. Or move with the mouse over the area and press F5.

The navigation tabs are divided into three groups. Tools section, Globals section and Object Data Section. We will cover the content of the different tabs in the corresponding section of the manual.

## Globals section

The Globals section contains everything that is not related to the currently selected object. But global. Render settings, View-, Scene- and World settings.

## Object Data Section

The Object Data section contains everything that is related to the currently selected object. From mesh data across material up to texture and particle system.

The content differs, dependent of the currently active object. For an Armature you will have other tabs than for a Mesh object, and other tabs for a Lattice object for example.

There are some general tabs though for all object types. Like Object, Constraints, Texture, or Physics tab.

## Properties Editor - Context menu

When you click into an empty area of the Properties editor then you call the context menu.

### Area

This menu contains general view functionality. And exists in most other editor types too.

### Horizontal Split

Splits the current view horizontally into two independent editor windows.

### Vertical Split

Splits the current view vertically into two independent editor windows.

### Duplicate Area into New Window

Duplicate Area into New Window makes the selected editor window floating. You can then drag it around at the monitor. It is not connected with the rest of the UI anymore.

A separated window cannot be merged into the main window again. You have to close it when not longer needed.

### Toggle Maximize Area

Displays the editor maximized with menus.

To return from the maximized view press hotkey ctrl + spacebar. Or reuse the menu item in the area menu.

### Toggle Full screen Area

Displays the editor maximized without menus.

To return from the full screen view press hotkey ctrl + alt + spacebar.

# File Browser

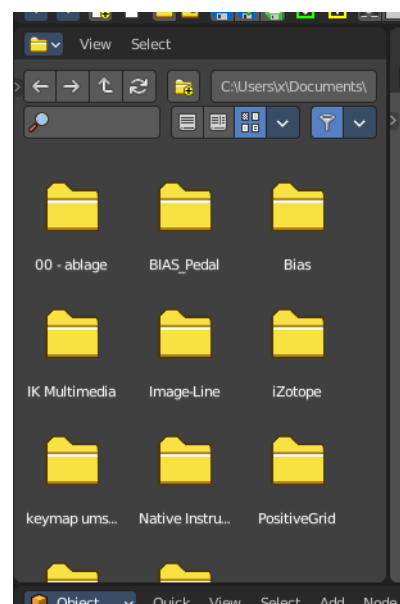

The file browser is an explorer dialog that allows you to browse for locations and files, and allows you to load and save them.

The file browser has multiple uses. While its often used for save/load, it can be kept open for other uses too.

In the file browser you can:

- Opening and Saving Blend files.
- Import/Export other file formats.
- Picking new locations for existing file-paths (images, video's, fonts... etc).
- Browsing inside other .blend files, when using *Append and Link*.

You can also keep the file selector open, as with any other window type. In this case the buttons to load files is removed. This is for example done in the Shader editor workspace. This allows you to drag files directly into the editor where you need it.

# File Browser Header

There are several tools in the header to find. The range goes from navigation elements across filters up to display options.

There are two header areas. The header area that contains the

navigation and filter elements. And the editor header like in a traditional editor. This header is hidden when you use the file browser as a file selector. But it is still available. It resides at the bottom, and can be revealed by clicking at the small triangle button down right.

For this content see Footer Header chapter below.

## Navigation

Navigate in the folder hierarchy.

## Previous Folder

Navigate to the previous folder.

## Next Folder

Navigate to the next folder.

## Parent File

Go upwards in the hierarchy.

## Refresh

Refresh the file list.

## New Folder

Creates a new folder.

## File path

The current directory.

## Search

Name Filter. Allows you to search for specific files and folders.

## Display As

### Vertical List

Displays the content of the file browser as a vertical list.

### Horizontal List

Displays the content of the file browser as a horizontal list.

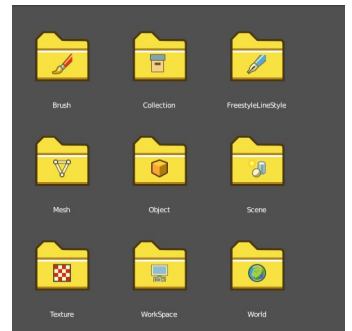

### Thumbnails

Displays the content of the file browser as thumbnails. This is especially of use for images or blend files with thumbnail preview.

When you link or append from a blend file then the thumbnails also shows folders with icons for the different content of the library blend file.

## Display Options

### Columns

First shot is from when in columns and horizontal list view. Second is from Thumbnails View.

### Size

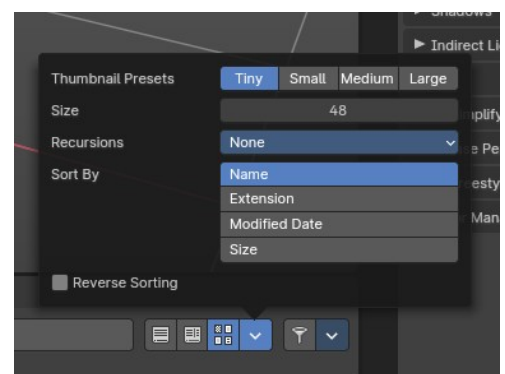

Display the size of the files.

### Date

Display the creation date of the files.

### Size

Thumbnail view - the size of the thumbnails.

## Thumbnail Presets

Thumbnail Presets – Quick sizes for the thumbnails

## Recursion

Adjust how deep the explorer should dig. Normally it just lists the content of the currently selected directory. But it is also possible to list the content of the folders three levels lower.

The recursion direction is always downwards. Default is None.

## Sort by

Sort the files by chosen method. The methods are self explaining.

## Reverse Sorting

Reverts the sorting direction.

## Filter

### Filter

Enable the filtering.

### Folders, etc.

The different file types that should be filtered. What is ticked here and what file types shows depends of what file browser you call. If you want to load a blend file. Or a FBX file from the File menu in the header. Or an image in the UV Editor for example.

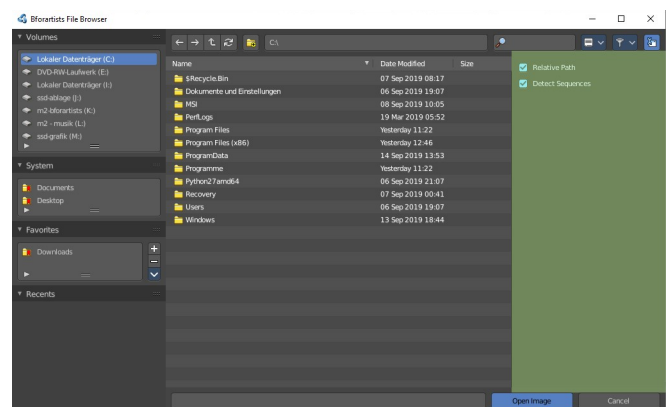

### Show Hidden

Shows hidden Dot files.

This is a Unix feature. Unix systems like Linux or Mac hides files from file browsers and explorers by having a dot before the file. A good example is the .htaccess file at servers. Show hidden Dot Files makes such files visible to the file browser.

## Toggle Region

Toggles the sidebar at the right. The sidebar contains various im- and export settings for the single file types.

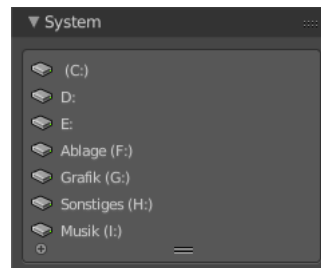

# Tool Shelf

The Tool Shelf at the left provides you with some panels for quick access to files and bookmarks.

## System Panel

Lists your drives.

## System Bookmarks

Lists some system libraries.

## Bookmarks

Add your own bookmarks. A direct bookmark towards the Downloads folder for example.

## Recent

A list of the recent accessed folders.

Greyed out folders are not longer existing directories. There is unfortunately no way to remove them from within Bforartists. You would need to do this manually in the History text files in the settings folder.

Under Windows this is the bookmarks.txt file in the Appdata folder.

## Clear recent

Removes the selected item from the recent panel.

# Sidebar

The sidebar is usually closed in most cases. Sometimes you need to open it. This can be done with a click at the Toggle Region button up right.

In the sidebar you will for example find the special Import or Export settings for the current file format. And here you will also find further settings. loading a Blend file you will just see two entries. When you append from a file then it's a bit more settings. And for file formats like FBX you will find all the settings for the current file format.

At the right you see the import dialog for FBX.

As an example, and to explain the two settings for loading a blend file:

## Load UI

Bforartists comes with the feature \*Load UI\* unticked. This means the Bforartists UI will not change when you load a scene. Here you can temporary enable to load the scene with the layout and UI arrangement in which the scene was saved.

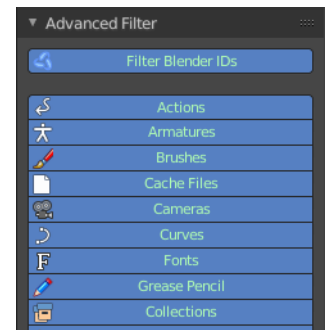

## Trusted Source

With Load UI you can also load script files, which can execute. This is a potential security risk when the file comes from an unknown source.

## Advanced panel

When you append from a blend file, then you will find an Advanced panel with further filter settings in the sidebar. This filter allows you to filter the content for exact object types.

# File dialog

The file dialog is the actual place where your files and directories gets listed.

## Click navigation.

Double clicking at a folder enters the folder. To go upwards in the hierarchy see Parent File button in the header.

## Double Click to load

Double clicking at a file loads the chosen file when you are in a load dialog. The file dialog will then close.

## Double click to save

Double clicking at a file overwrites the chosen file when you are in a save dialog. The file dialog will then close.

## Select and load more than one file

Holding down shift allows you to select and to load more than one file.

## Box select

You can drag a box around the files by simply left clicking and moving the mouse.

## Renaming

You can rename files and folders from within this list. Holding down ctrl and clicking at a file enters the edit file name mode.

## File Name

The file that you want to load or to save.

## Open / Save

Open or save the current file(s).

## Cancel

Cancel the loading or save process and close the file browser.

# Footer / Header

The footer is hidden by default when you call the file browser to load and save scenes and files. But contains some more functionality. And when you integrate the file browser into a workspace then the header shows at the top. In the Shading workspace for example.

You can reveal the footer by clicking at the triangle button at the right.

And then you will see the footer bar. Which will reveal two menus. View and Select.

## View Menu

### Source List

Shows or hides the tool shelf at the left side.

### File Path

Shows the header region with the file path and the navigation and filter elements.

### Frame selected

Centers the selected elements.

## Area Menu

Area is a menu with window related settings.

### Horizontal Split

Splits the editor horizontally into two editors.

### Vertical Split

Splits the editor vertically into two editors.

### Duplicate Area into new Window

Creates a floating window out of the current editor.

### Toggle Maximize Area

Displays the editor maximized with menus.

To return to split view press hotkey Ctrl Up Arrow, or reuse the menu item in the View menu.

### Close Area

Closes the area window.

## Pie Menus

Every editor usually has also a few pie menus that can be called by hotkeys. Here you can manage the hotkeys. And see which pie menus even exists.

### View

Reveals the View pie menu.

---

## Select menu

### Box Select

Allows you to box select files. Note that this is an old obsolete operator. You don't need to press the hotkey anymore for box select.

### Inverse

Inverts the selection.

### None

Select none.

### All

Select all.

## Files context menu

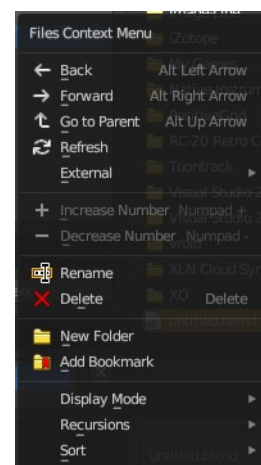

When you right click into the view at one of the browser items, then a files context menu opens. This menu comes from the File browser, and contains a few menu items that are not valid for the asset browser. Like create a folder. And the importer does not have the possibility to increase Number for example.

### Back

Go to previous folder.

### Forward

Go to next folder.

## Go to Parent

Go upwards the hierarchy by one.

## Refresh

Refresh the file list.

## External submenu

The menu content differs, dependant from which editor you call the file browser, and which menu item is chosen.

## Open

Opens the file in Bforartists.

## Open Folder

Opens the folder that contains the file in the explorer.

## Command Prompt Here

Opens the command prompt at the location of the file.

## Properties

Shows the file properties.

## Edit

Opens the file in the corresponding software that is defined as the software to open the file with. A bitmap with Windows Paint for example.

## Print

Prints the file.

## Play

Plays the selected file. A movie in the Windows Media Player for example.

## Find

Search for files of this type.

## Show

Show this file in the explorer

## Browse

Browse this file.

## Preview

Preview this file.

## Install

Install this file.

## Runas

Run this file as a specific user.

## Find in Folder

Search for items in this folder.

## Increase Number

Increases the number at the selected data file in the file name edit box.

## Decrease Number

Decreases the number at the selected data file in the file name edit box.

## Rename

Rename the selected item.

## Delete

Delete the selected item.

## New Folder

Add a new folder.

## Add Bookmark

Adds a bookmark in the file browser tool shelf in the Bookmark panel.

## Display Mode

Display the content as a list or as icons.

## Display Size

Set the display size of the file browser to four predefined sizes.

## Recursion

Recursion is a menu where you can adjust how deep the explorer should dig. Normally it just lists the content of the currently selected directory. But it is also possible to list the content of the folders three levels lower.

The recursion direction is always downwards. Default is None.

## Sort

Sort the content by the chosen method.

## Introduction

Bforartists comes with a default asset library – registered by addon. This is enabled by default. With this asset library you can find numerous default assets to get you up and running with your art quickly and efficiently.

## The Asset Browser Library

The Asset Browser is an editor in the Asset Workspace that gives you some standard lighting settings for the Cycles and Eevee renderer, objects in collections, node groups, materials and more. It contains for example the classical three-point setup. But also some basic volumetrics examples – or a shader ball or color checker reference stand.

The default library addon can be turned off in the User Preferences.

*Note that the Eevee light setup is rudimentary. Eevee is a realtime render engine. To achieve more realistic results you may want to use Light probes, and bake the lights and shadows. This cannot be done by the addon though. Light probes requires a scene, light and object specific setup.*

## Library Contents

To select the Default Library, choose it from drop-down box that contains the libraries that comes with Bforartists. Here you can select what asset you want to load.

The assets are grouped by categories.

## Categories

- Collections
  - Lights
  - Static Meshes
    - Backgrounds
    - Utility
- Materials
  - Ceramic
  - Cloth
  - Foilage
  - Glass
  - Liquids
  - Metals
  - Misc
  - Paint
  - Plastic
  - Rubber
  - Templates
  - Utility
  - Wood
- Shader nodegroups
  - Color
  - Layers
  - Mapping
  - Masks
  - Patterns
  - Shaders
  - Shapes
  - Utility

## Simple Usage

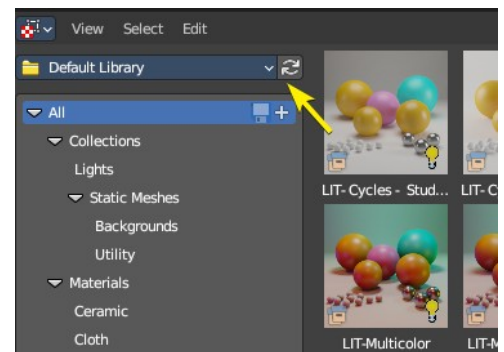

### Preparation

Select the **Assets Workspace** or alternatively change and editor by toggling the Hide Editor Type and changing it to the Asset Browser.

Once you have an asset browser open, select the Default Library from the drop down to the top left of the editor.

If you don't see any assets, press the refresh icon.

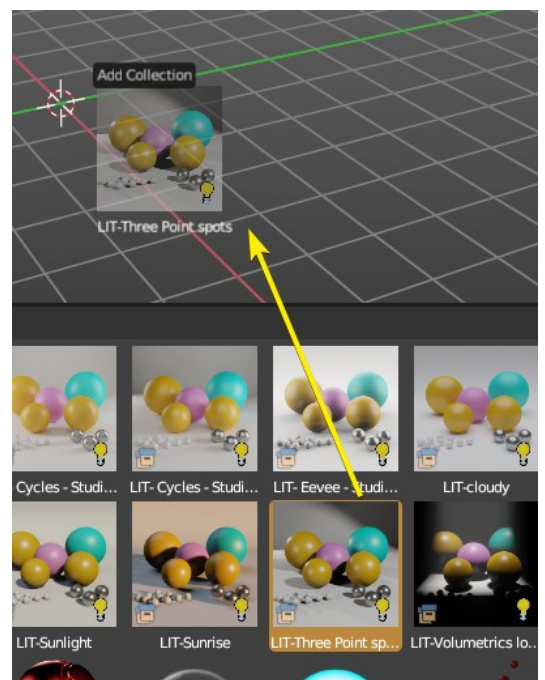

### Loading Assets

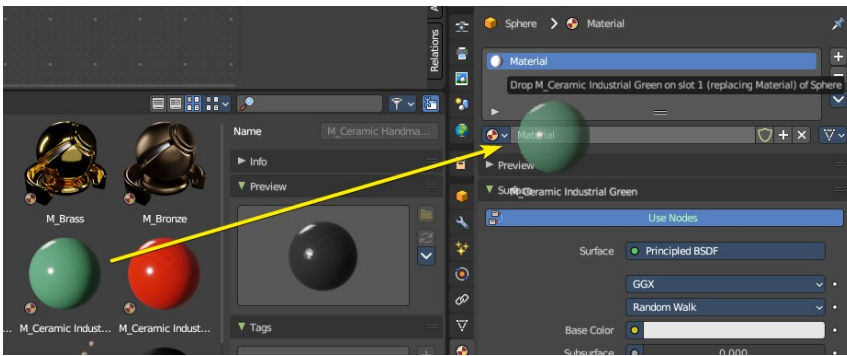

Click on any categories in the left sidebar, then click and drag on an item to then add it into either the Node editors or the 3D View.

The asset and editor context may influence where you can drag and drop. Example: A collection can only be added to the 3D Viewport, but a Node Group can only be added to the Node Editor in the correct mode (Shader, Geometry Nodes, etc)

You can also drag and drop the assets onto data slots.

## Collections - Lights

Here you can get an overview how the result looks like for the different lighting set-ups. Note that just the Cycles results are showing here.

Be careful with the volumetrics examples. Especially the Musgrave example can render eons.

## Collections – Static Meshes

This category contains static meshes with the prefix “SM\_”, which are collections with objects and materials to be used in various situations.

## Backgrounds

This category contains quick photographic backdrops.

## Utility

This category contains utility meshes for object scale, lighting and others, including a shader ball.

## Materials

This category contains materials useful to quickly apply materials to your objects via drag and drop. You can then later modify the materials in the Properties Editor Materials tab or in the Shader Editor.

### Ceramic

Procedural ceramic materials

### Clay

Procedural ceramic materials

## **Fabric**

Procedural fabric materials

## **Foliage**

Foilage materials

## **Glass**

Procedural glass materials

## **Liquid**

Procedural liquid materials

## **Metal**

Procedural metal materials

## **Miscellaneous**

Various materials for miscellaneous use cases

## **Paint**

Procedural paint materials

## **Plaster**

Procedural plaster materials

## **Plastic**

Procedural plastic materials

## **Rubber**

Procedural rubber materials

## **Templates**

Material templates to help setup various material setups

## **Utility**

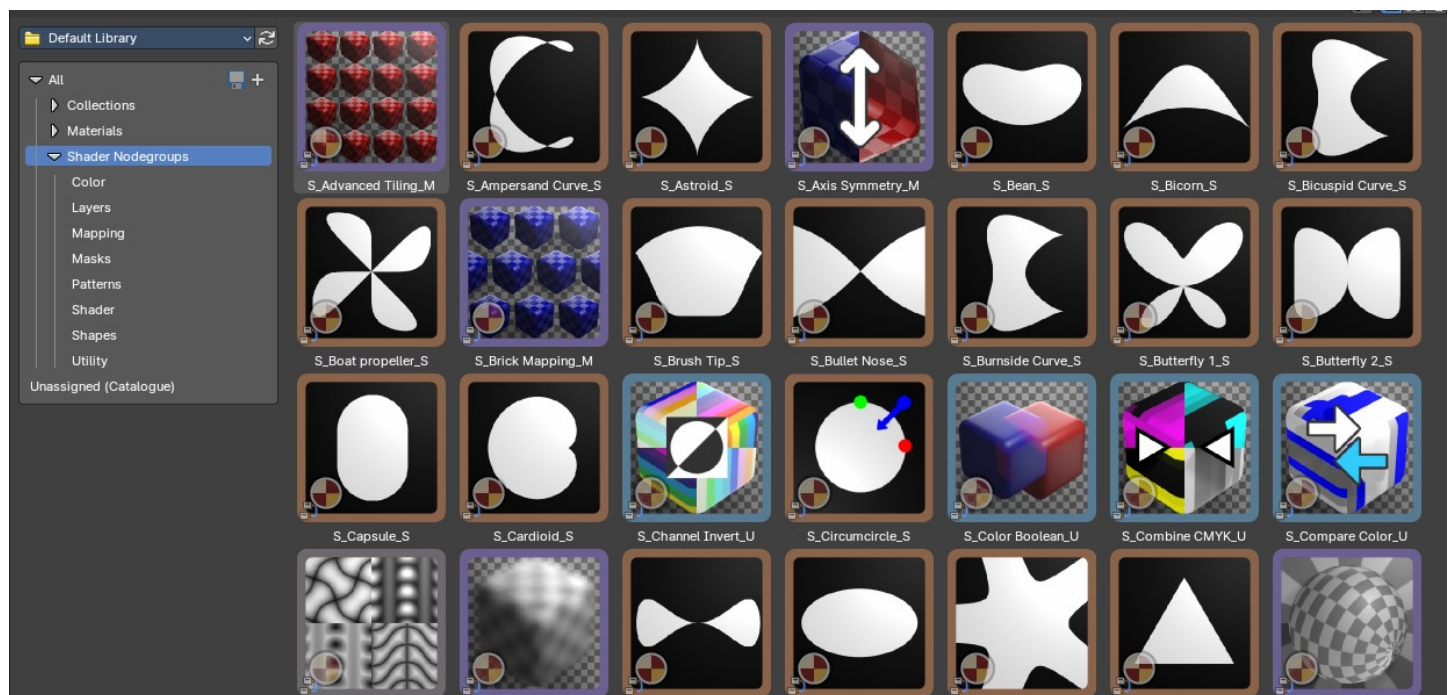

Varopis utility materials

## **Wood**

Procedural wood materials

## Shader Nodegroups

This category contains shader nodegroups useful to create procedural materials in the Shader Editor.

### Color

These nodegroups are used to define color halftone effects or a simple PBR layer mix node.

### Mapping

These nodegroups are used as UV mapping nodes to define vector interactions from various texture projections types, from tiling to deformations.

## Masks

These nodegroups are useful to create masks for edgewear and other effects when layering materials or textures.

Most of these edge masks nodes work exclusively with Cycles, though one works with Eevee. They also contain edge noise, edge breakup and ambient occlusion masking for more control.

They work best when you bake the results as a texture mask to your meshes that have been unwrapped.

## Patterns

These nodegroups are useful to create procedural patterns for masks or textures in your materials. Each comes with their own set of parameters and data outputs, from UVs, tile position, random color, random values and more.

## Shader

These nodegroups are useful to select shaders via ID or color switches.

## Shapes

These nodegroups are procedural shapes that you can use with a combination of mapping and pattern nodegroups to then create masks or new patterns. Useful for creating new textures, brushes and motion graphics.

## Utility

These nodegroups are useful to assist various miscellaneous tasks with shader nodes from normals, colour and masks.

## Essentials Asset Library

Bforartists comes with a default asset library created by Blender. This asset library is a special one that only allows to append assets, there is no way to link in the assets.

## The Asset Browser

The Asset Browser is an editor in the Asset Workspace that gives you some essential nodegroups mostly for curves objects and curve data geometry nodes modifiers and node groups.

## Library Contents

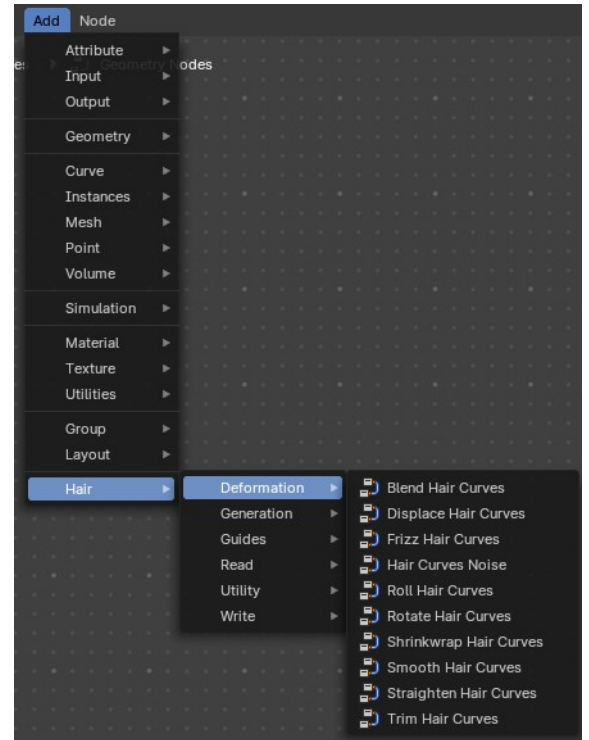

To select the Essential Library, choose it from drop-down box that contains the libraries that comes with Bforartists. Here you can select what asset you want to load.

The assets are grouped by categories.

# Introduction

## The Asset Browser Library and Modifier assets

Hair nodes are Geometry node groups found in the Essentials Library included with Bforartists. They differ from the other nodes in the add menu due to being mid level node groups instead of individual low level nodes.

These hair nodes are also available as Modifier assets. When used as a Modifier asset, these adds the same node group as you would do it in the geometry node editor. Which means you can control these node groups in the modifier stack now instead of the geometry node editor.

**Note:** Curves objects is usually a mesh only functionality. But shows for all other object types too. You can use some of the these node groups with Curve data also.

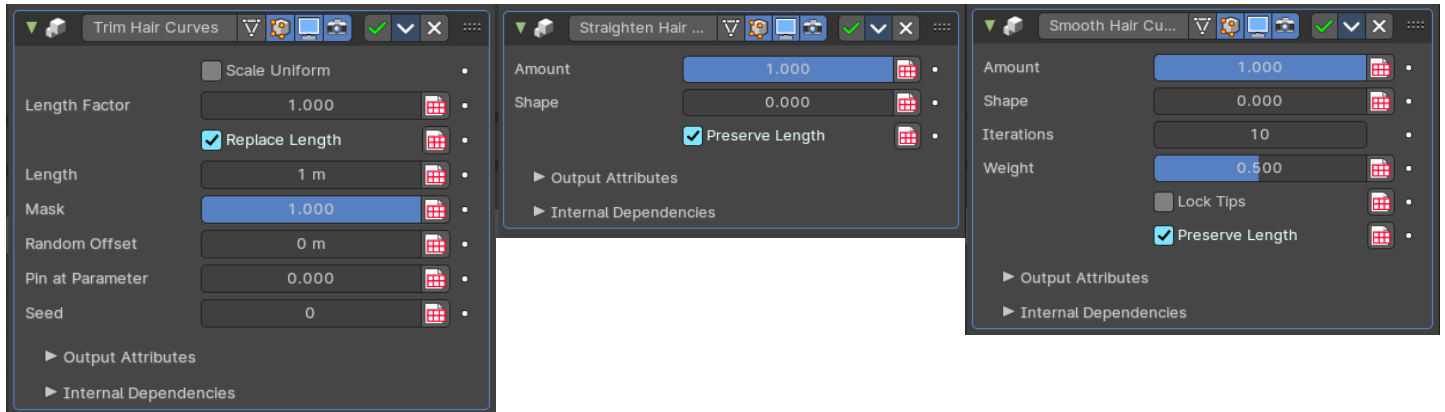

## General functionality

Every node group has a set of parameters with tooltips, each can help you understand what each node group does. You can view the properties in the modifiers stack in the Properties Editor or directly in the Geometry Nodes Editor.

All node groups also have an Output Attributes and Internal dependencies tab. If the hair node has output attributes or internal dependencies depends of the hair node.

## Examples of properties:

## Categories Overview

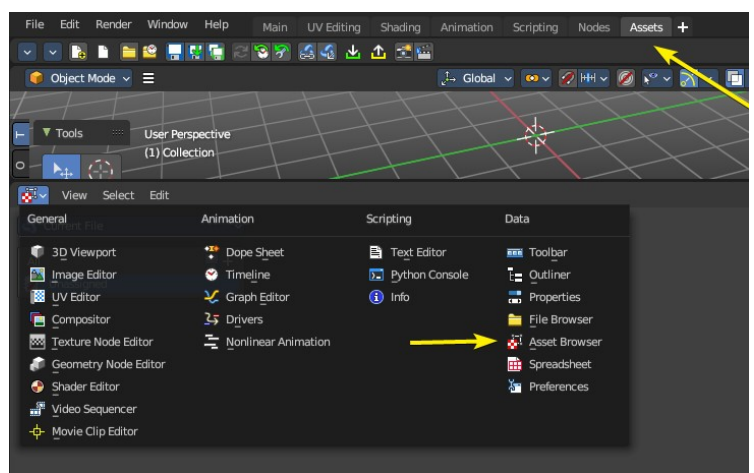

- Hair
  - Deformers
  - Generation
  - Guides
  - Read
  - Utility
  - Write
- Normal

## Simple Usage

### Preparation

Select the **Assets Workspace** or alternatively change and editor by toggling the Hide Editor Type and changing it to the Asset Browser.

Once you have an asset browser open, select the

Default Library from the drop down to the top left of the editor.

If you don't see any assets, press the refresh icon.

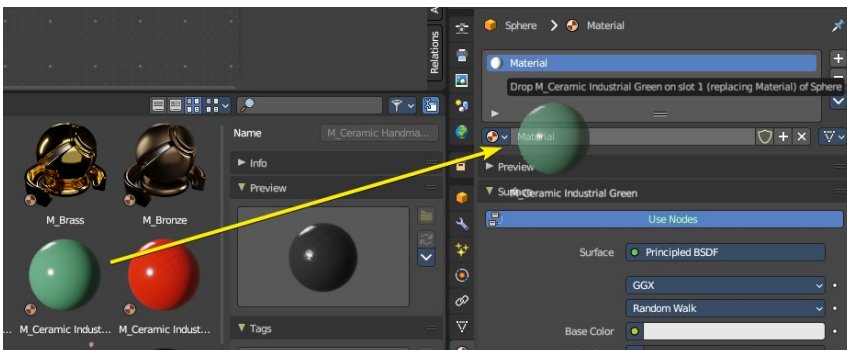

## Loading Assets

Click on any categories in the left sidebar, then click and drag on an item to then add it into either the Node editors or the 3D View.

The asset and editor context may influence where you can drag and drop. Example: A collection can only be added to the 3D Viewport, but a Node Group can only be added to the Node Editor in the correct mode (Shader, Geometry Nodes, etc)

You can also drag and drop the assets onto data slots.

## Categories

### Hair – Deformations

This group of hair node groups are useful for deforming the curves object hair strands. They can also be used on curve objects or curve data in other geometry nodes.

#### **Blend Hair Curves**

Blends the shape between multiple hair curves in a certain radius together.

#### **Frizz Hair Curves**

Deforms hair curves using a random vector per point to frizz them.

#### **Hair Curves Noise**

Deforms hair curves using noise texture.

#### **Roll Hair Curves**

Rolls up hair curves, starting from their tips.

#### **Rotate Hair Curves**

Rotates each hair curve around an axis.

#### **Shrinkwrap Hair Curves**

Shrinkwrap hair curves to a mesh surface from below and optionally from above.

## Smooth Hair Curves

Smooths the shape of hair curves.

## Hair – Generation

The curves object node groups contain methods to generate new hair strands.

### Duplicate Hair Curves

Duplicates hair curves a certain amount of times in the given radius.

### Generate Hair Curves

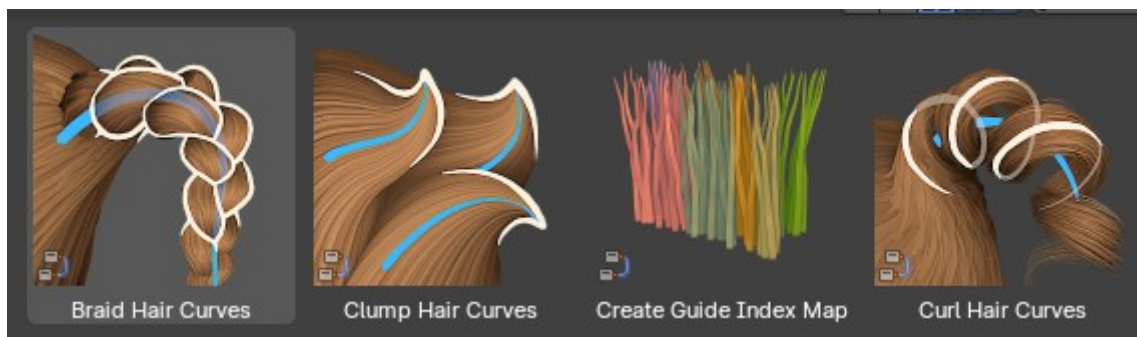

Generates new hair curves on a surface mesh.

### Interpolate Hair Curves

Interpolates existing guide curves on a surface.

## Hair – Guide

### Braid Hair Curves

Deforms existing hair curves into braids using guide curves.

### Clump Hair Curves

Clumps together existing hair curves using guide curves.

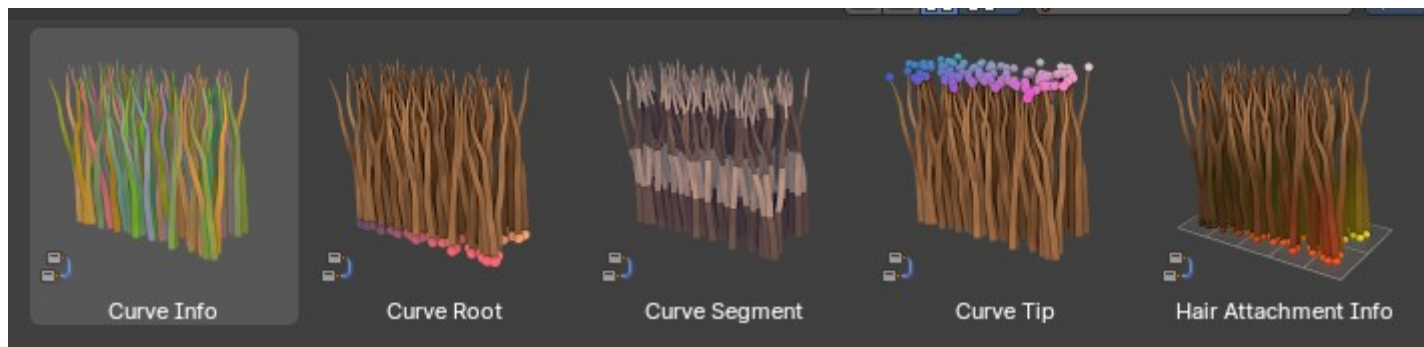

### Create Guide Index Map

This creates a new index map as an attribute that maps each curve to its nearest guide via index to assist in using an index field per hair cluster.

### Curl Hair Curves

Deform existing hair curves into curls.

## Hair – Read

### Curve Info

Reads and gets the individual curve data as a field, including the index, curve ID, length, direction, random and surface UV.

### Curve Root

Reads information and gets data from every curve’s root point.

### Curve Segment

Reads information from each point in from every curve’s previous curve segment.

### Curve Tip

Reads information and gets data from every curve’s tip point.

### Curve Attachment Info

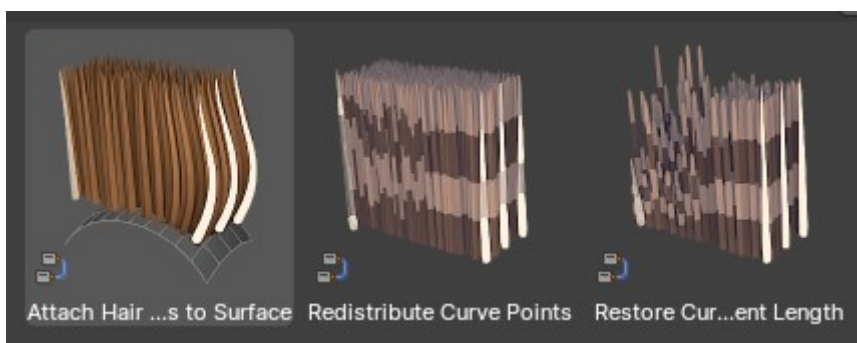

Reads information and gets data from the attach point regarding a surface mesh.

## Hair – Utility

### Attach Hair Curves to Surface

Attaches hair curves to a surface mesh.

**Note:** *Bare in mind you will need to parent the hair curves to a mesh before you can attach the curves to a surface mesh.*

### Redistribute Curve Points

Redistributes existing control points evenly along each curve.

## Restore Curve Segment Length

Restore the length of each curve segment using a previous state after deformation. Consider this like a bypass node.

## Hair – Write

### Set Hair Curve Profile

Set the radius attribute of hair curves according to a profile shape.

## Normals

This category only contains one node for procedural autosmoothing of normals.

### Smooth by Angle

Smooth normals by angle procedurally. Anything above a certain angle threshold will be marked as sharp.

# Asset Browser

The Asset browser is an explorer dialog that allows you to store assets, and reuse them at a later point.

Assets can be everything. Objects, scenes, grease pencil strokes and so on.

The asset browser interface is divided into several areas.

Header (green)

Categories (blue)

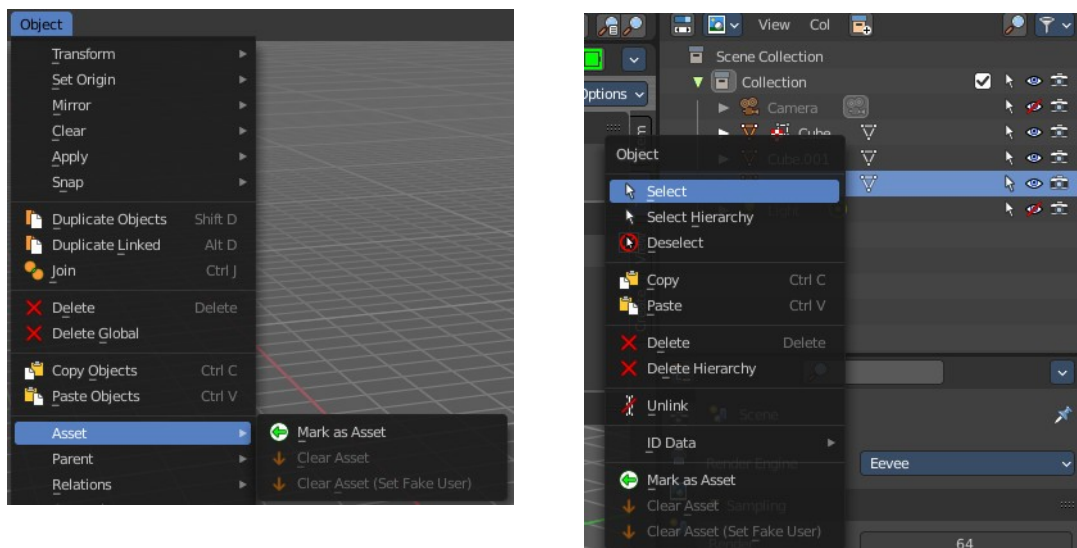

Sidebar (yellow)

Content area (no color)

## How to

### Asset handling

To insert or remove an asset you can use the right click menu in the outliner. Or the object menu in the 3d viewport. Mark Asset and Clear Asset.

When it is something like a material or a texture, then you can also right click at the menu in the data prop. This will also reveal a menu where you can add or remove the asset.

Dragging items into the browser is currently not supported. The other direction works though. You can drag assets from the browser into the 3d view.

Poses can be inserted in pose mode. But how is currently not documented.

## Asset Library

There are two ways to deal with assets. You can either store them in the current blend file for later use. This is the “Current file” method.

Or you can switch to “User Library”, and/or create an external library from a fixed path.

If you’d like to view all, select the “All” category.

To setup your external library, go to Preferences > File Paths > Asset Libraries to add this path to your asset libraries then. You can also do the same from header menu Catalog > Asset Library Paths.

You can add more than one asset library from the preferences.

## Drag n Drop of materials

Materials can be dragged directly at the material slots in the Properties Editor.

Header

There are several tools in the header to find. Menus, and a few options.

## Header - View menu

The view menu contains view related functionality.

### Source List

Shows or hides the tool shelf at the left side.

### File Path

Please ignore. This entry is a bug. The asset browser shares the code with the file browser.

### Frame Selected

Scrolls the selection into view.

### Display Size

The display size for the assets.

### Area Menu

Area is a menu with window related settings.

### Horizontal Split

Splits the editor horizontally into two editors.

### Vertical Split

Splits the editor vertically into two editors.

### Duplicate Area into new Window

Creates a floating window out of the current editor.

### Toggle Maximize Area

Displays the editor maximized with menus.

To return to split view press hotkey Ctrl Up Arrow, or reuse the menu item in the View menu.

### Toggle Fullscreen Area

Displays the editor maximized without menus.

To return from the full screen view press hotkey Alt F10, or use the little button that appears up right when you move the mouse in this corner.

## Close Area

Closes the editor.

# Header - Select menu

Select functionality.

## Box Select

Allows you to box select files. Note that this is an old obsolete operator. You don't need to press the hotkey anymore for box select.

## Inverse

Inverts the selection.

## None

Select none.

## All

Select all.

# Header - Catalog menu

## Undo

Undo of the last edit operation.

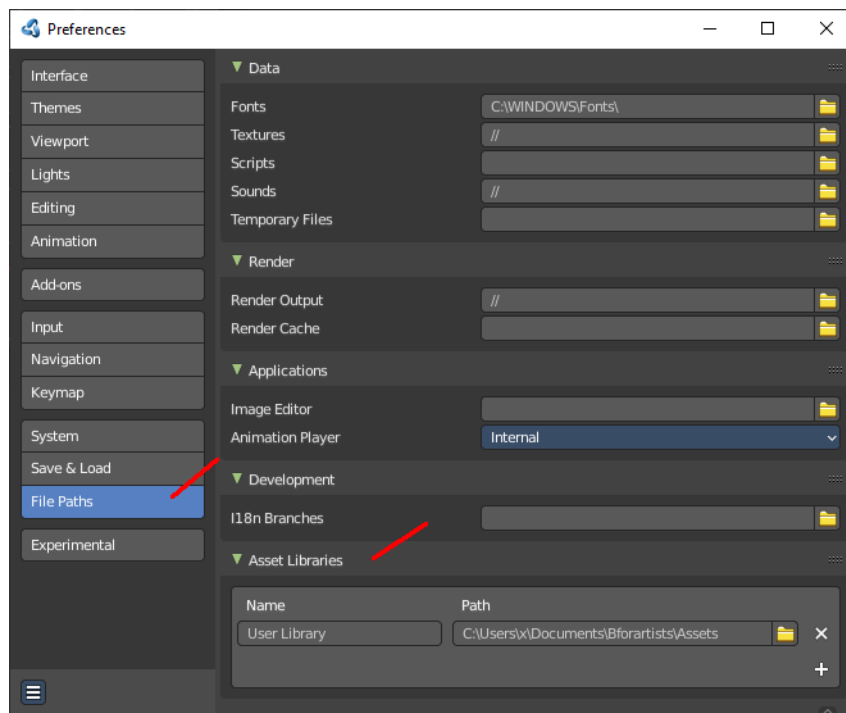

## Redo

Redo of the last edit operation.

## Asset Library Paths

Opens the file browser at the Paths tab. Here you can show, edit, and add paths to new asset libraries.

## Save Asset Catalogs

Save all changed asset catalogs.

## New Asset Catalog

Add a new asset catalog.

# Header - Asset menu

This menu contains asset related menu items.

## Paste as new asset

Pastes a previously copied asset.

## Create Pose Asset

Creates a pose asset from the selected armature.

**Note:** When you create a Pose Asset, it will capture what you see in the viewport from the active camera or view.

## Use

To create a Pose Asset, follow these step:

1. In the 3D View, select your Armature object and go into Pose Mode
2. Select the bones you want to store as a pose
3. In the Asset Browser Header Asset menu, use the operator Create Pose Asset
4. This will create a Pose Asset in the Unassigned (Catalogue) category in the Current File.
5. Click on the new Pose Asset in the Asset Shelf or Asset Browser to apply. Press and drag to apply with a

slider strength.

6. You can alternatively right click on the Pose Asset for alternative methods of applying the pose.

## Header - Tools and Options

### Drop Instance Collections at Origin

Drop the asset at mouse position or at the world origin in the 3d view.

### Drop Collections as Instances

Drop the asset as instances of another object.

Note that this feature disables Drop Instance Collections at Origin since the asset now drops at the origin of the object.

### Import Method

Allows you to define how to import the assets.

### Follow Preferences

Use the import method as defined in the preferences.

### Link

Link the asset at import.

### Append

append the asset at import.

### Append (Reuse Data)

append the asset at import. But avoid multiple copies of the asset.

### Display Mode

Allows you to switch between list view and thumbnail preview view.

## Vertical List

Displays the content of the file browser as a vertical list.

## Horizontal List

Displays the content of the file browser as a horizontal list.

## Thumbnails

Displays the content of the file browser as thumbnails. This is especially of use for images or blend files with thumbnail preview.

## Display mode options

### *Vertical / Horizontal List*

Shows the assets in a vertical list or in a column based horizontal list.

### Size

Toggles the column with size information.

### Date

Toggles the column with date information.

### *Thumbnails*

### **Tiny / Small / Medium / Large Buttons**

Preset display size of the thumbnails for the assets.

### Size

The display size of the thumbnails for the assets. The range for these thumbnails goes from tiny with 64 pixels up to large with 256 pixels.

---

## Search

Name Filter. Allows you to search for specific files and folders.

## Filter

Allows you to filter the assets library in various ways. The menu items should be self explaining.

## Toggle Region

Toggles the sidebar at the right. The sidebar contains various im- and export settings for the single file types.

## Drop collection as Instances

When it's on, you link collections as instances. When off, it links to scene. Default is off.

## Drop collection at World Origin

When it's on, you link or append collections or collection as instances to world origin (center). When off, it links or appends to the mouse cursor. Default is off.

**Note:** When you link a collection to scene, not as an instance, and the world to origin is off, any concurring instances of the linked collection will have an offset. This is used to prevent any collection instance offsets to opt-in to linking in collections to scene at world origin, to later override or use as instance.

## Import Method

### Follow Preferences

Use the import method set in the Preferences for this asset library, don't override it.

### Link

Import the assets as linked data

### Append

Import the assets as copied data, with no link to the original asset data

### Append (Reuse Data)

Import the assets as copied data-block while avoiding multiple copies of nested, typically heavy data. For example the textures of a material asset, or the mesh of an object asset, don't have to be copied every time this

asset is imported. The instances of the asset share the data instead.

## Tool shelf

The toolshelf shows the different catalogs that you can use to store your assets.

These catalogs are currently dysfunctional. You can just add or remove the categories. But not insert assets to it.

## Asset Library chooser

Here you can choose what asset library to use.

## Current File

Uses the current Blend file as the asset library. All assets are stored into the current blend file. And this means that when you remove objects from the scene, then the assets in the assets library will also vanish.

## User Library

Uses the blend file in the path that is defined in the user preferences as the asset library.

Working with more than one blend file is currently not supported.

## Refresh

With a user library you will get a refresh button besides the asset library chooser. Refreshes the content.

## Asset Catalogs

Asset catalogs allows you to organize your assets.

Note that asset catalogs does not work with the external asset libraries. Just with the asset library in the current file.

First save your file. The method does not work at a blend file that is not saved yet.

Then create your catalog, and name them.

Then select one of your assets. And drag it onto the catalog that you want to add it to.

Finally, save the asset.

## Save Asset Catalogs

Saves the current asset catalog to file and make the changes permanent.

## New Asset Catalog

Creates a new asset catalog. Asset catalogs can be nested too.

## Unassigned

The assets that are currently not in a catalog.

## Asset catalog right click menus

Note that the Edit Source button is a developer feature.

### Right clicking at the All item

#### **Mark as asset**

Marks the object as an asset. Dysfunctional in this context.

#### **Clear Asset**

Removes all assets.

### Right clicking at one of the catalog items

Content depends if you have an asset selected or not.

#### **New Catalog**

Creates a new nested catalog inside of the current catalog.

## Delete catalog

Deletes the catalog and all of its childs.

## Rename

Rename the current catalog.

## Mark as asset

Marks the object as an asset. Dysfunctional in this context.

## Clear Asset

Removes all assets.

# Sidebar

At the right side you will find the Sidebar. It is usually hidden. But can be revealed by a click at the litte triangle button, or with a click at the Toggle Region button in the header at the right.

## Name

The name of the asset. Here you can also rename the asset. Note that the name of the asset in the view does not refresh immediately at the moment. You can force a refresh of it in the Preview panel by clicking at the Generate Preview button

---

## Info Panel

Some additional infos about the asset.

## Source

A source that can't be edited for the Blender developers.

## Description

Add a description for the asset.

## Author

Add the name of the author of the asset.

## Preview Panel

A preview of the asset. By default the same image that you see in the view when you create the asset.

## Load Custom Preview

Opens a file browser where you can choose a custom icon for this asset.

## Generate Preview

Generates a preview icon from the content. Note that this will reset the custom icon.

## Tags Panel

Enter custom tags for this asset. This tags allows you to sort your assets by tag.

### Tags List

The list of the current tags.

### Drag handler

Allows you to resize the list.

### Search

Search the list. This search can be expanded by clicking at the little triangle button down left.

## Add Asset Tag

Adds a tag to the tag list. This tag can be renamed in the list.

## Remove Asset Tag

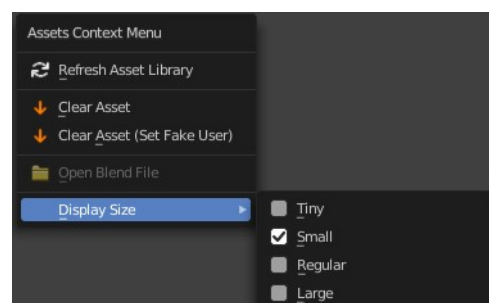

Removes the selected tag from the tag list.

## Assets context menu

When you right click into the view then an Asset context menu opens.

## Refresh Asset Library

Refresh the file list.

## Clear Asset

Removes the asset from the asset library.

## Clear Asset ( Set Fake User)

Removes the asset from the asset library. But sets it to fake user, so that it remains in the scene.

## Open Blend File

Opens the path for the blend file that contains the active asset. Just active with User Library.

## Display Size

Set the display size of the file browser to four predefined sizes.

## Pose Assets context menu

When you right click on a pose asset in the Asset Browser or 3D View Asset shelf, you get extra options to help apply the pose. To use them, make sure you have a compatible armature selected, are in Pose Mode and have the bones you'd like to pose selected.

*Note: Pose action assets are single keyframe action clips marked as assets either from the NLA or the Dopesheet editors. Animation keyframe sequences cannot be marked as assets.*

## Apply Pose

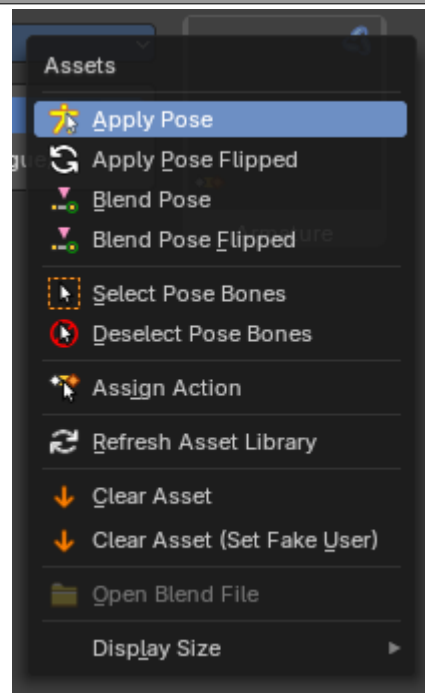

Apply the given pose action to the active rig. When you select this, this will apply the pose to selected bones.

## Apply Pose Flipped

Apply the given pose action to the active rig with a flipped axis. When you select this, this will apply the flipped pose to selected bones.

Flipping happens usually from bones labeled .L and .R

## Blend Pose

Blend the given pose action to the active rig. This is useful to interpolate from the original pose to the new pose. When using, you will see a slider in the asset browser header giving you a degree of blend.

## Blend Pose Flipped

Blends the selected bones with the flipped Pose asset.

## Select Pose Bones

Select those bones used in this pose action. This will select all the necessary bones you need to apply the pose effectively. If you have no bones selected, the pose will not apply. Poses only apply to bones that are selected.

## Deselect Pose Bones

Deselect those bones used in this pose action. This will ultimately clear the selection based on the pose action bones defined in the marked action clip.

## Assign Action

Set the pose action as the active action on the active object. This will ultimately load the pose action animation clip to the Action Editor of the Dopesheet, allowing you to edit the pose. This only works in the source file with the marked poses.

## Spreadsheet

The Spreadsheet Editor allows you to inspect geometry attributes.

The geometry nodes editor allows you to especially inspect specific nodes and their output.

Geometry nodes have a switch for that in the header, which can be turned on or off.

## Editortype Menu

Bforartists is made of several editor types. Headers can display a menu where you can switch to other editor types.

This menu is hidden by default. It is meant to edit the layouts, and should not be necessary for regular work. You can reveal it in the header right click menu.

## Header tools and options

### Object Evaluation State

Display the data of an object at different states of its evaluation.

## Evaluated

Display the data from object with all modifiers applied.

## Original

Display the data from original object without any modifiers applied.

## Node

Display the data from the currently active node in the geometry node editor. The active node has the Geometry node output icon in the header on.

## Geometry Component Type

Part of the geometry to display data from.

### Mesh

Mesh component containing point, corner, face and edge data.

### Point Cloud

Point cloud component containing only point data.

### Instances

Display which objects and collections are instanced and their transforms.

## Attribute Domain

Attribute domain to display.

### Vertex

Display attributes that are stored per vertex.

### Edge

Display attributes that are stored per edge.

### Face

Display attributes that are stored per face.

### Face Corner

Display attributes that are stored per face corner.

## Toggle Pin

Keep the data from the pinned object visible, even when another object becomes the active one.

## Name of the object

The name of the selected object. This is a breadcrumb menu. It can be collapsed.

## Selected Only

This option is only available if the object is in Edit Mode. When checked, only data for the selected mesh elements is shown.

## Row Filter

Turn on or off the row filters defined in the sidebar.

# Tool Shelf

The tool shelf allows you to filter out the data that you want to look at.

▼ Mesh		shade_smooth	material_index	normal		
Vertex	8	<input type="checkbox"/>	0	-1.000	-0.000	0.000
Edge	12	<input type="checkbox"/>	0	0.000	1.000	0.000
Face	6	<input type="checkbox"/>	0	1.000	-0.000	0.000
Face Corner	24	<input type="checkbox"/>	0	0.000	-1.000	0.000
Curves	4	<input type="checkbox"/>	0	0.000	0.000	-1.000
Control Point	0	<input type="checkbox"/>	0	0.000	-0.000	1.000
Spline	0					
Point Cloud						
Point	0					
Instances	0					

# Main region

Displays the list of the actual content. This content is dependant of the chosen data types.

	position X	position Y	position Z
0	-1.000	-1.000	-1.000
1	-1.000	-1.000	1.000
2	-1.000	1.000	-1.000
3	-1.000	1.000	1.000
4	1.000	-1.000	-1.000
5	1.000	-1.000	1.000
6	1.000	1.000	-1.000
7	1.000	1.000	1.000

# Sidebar

Here you can define row filters to filter out values in the corresponding columns and rows that you don't want to display.

The filter can then be turned off and on with the filter button in the header.

Note that the sidebar is closed by default. Click at the little triangle button to open it.

To create a filter, press the Add Row Filter button, then write the column type you would like to filter.

## Row filter panel

### Header

The header allows you to close and open the filter panel by clicking at the triangle button at the front.

### Enabled

Enable or disable this filter

### Title string

Some rows provides you with further informations in the header. In this case the position of the original geometry.

### Remove Row Filter

Removes the filter.

### Drag handler

This handler allows you to reorder the panel above or below other panels.

## Panel content

### Column

To filter out a row you need to type in the name of the row. Attention, this name is case sensitive.

### Operation

The filter method to filter out values.

### Value

The vector values allows you to set a base value for the single vectors. A position has for example 3 values. A UV map is 2d, and so you just have two values.

### Threshold

Just with operation method Equal to.

Allows you to define a threshold in which the "equal to" operation is evaluated. So that a value of 10.001 is still considered as in range for a value of 10 for example.

## Footer

The status bar in the footer shows how

many rows and columns there are and how many have been filtered out.

# Preferences

The Preferences is the place where you can tweak several settings to your needs. It can be opened in the Edit menu in the top bar.

The Preferences contains several tabs. And every tab contains several rows or panels with content. We will go through them one by one.

When you have changed something, and want that changes to be permanent, then you are required to save the user settings. See the Save User Settings button in the header.

## Navigation Sidebar

At the left side you will find the navigation elements to access the different categories. At the bottom resides the Save Preferences menu.

## Save Preferences menu

### *Auto Save preferences*

Changes at the preferences are saved automatically when Auto Save Preferences is ticked. When this option is off, then changes needs to be saved manually. When you don't save the changes, then Bforartists loads the next time with the status before the changes.

### *Save current State*

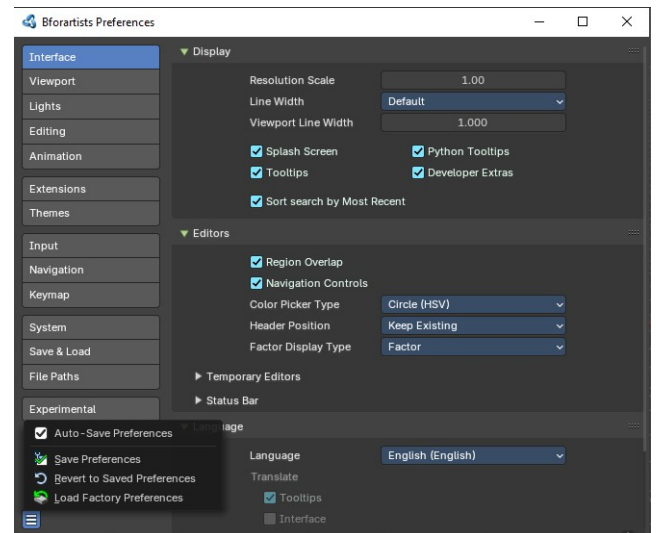

Manually saves the current state.

### *Revert to Saved*

This option is just available when Auto Save preferences is off. It reverts the settings to the last saved state.

### *Load Factory Settings*

Resets the settings to the factory defaults.

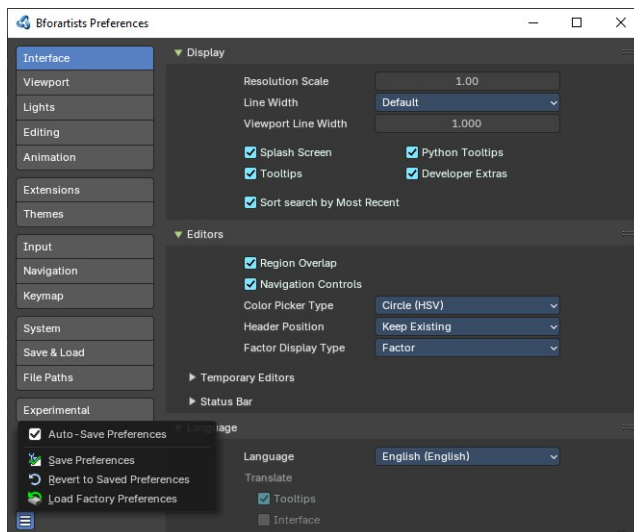

## Note

Not everything can be changed from the Preferences. Everything regarding layout is stored in the Startup File, and not in the Preferences. So when you want to save a layout change then you have to save the startup file. The menu item is right above the Preferences button in the Edit menu.

# Interface Tab

The Interface category contains settings to change how UI elements are displayed and how they react.

## Display Panel

### Resolution Scale

At 4K displays the whole UI elements are usually ways too small. Scale the whole UI size display by moving the slider to the needed value.

### Line Width

Define the size of the line between the editors. This is a theming setting.

### Viewport Line Width

Changes the appearance of only lines in the 3D Viewport.

### Splash Screen

Display the Splash Screen when starting Bforartists.

## Tool tips

Display tool tips in the UI. With this feature unticked you won't see any tool tips anymore. It is not recommended to turn this feature off. The icon buttons needs the tool tips to display the tool name.

## Python Tool tips

Every tool tip can also display the Python code tag for the tool. It may look like noise in the first moment. But can give you some further hints here and there. Some tool tips, like the Node editor buttons, doesn't have a proper tool description by design. Here the Python tool tip can tell you the function when you turn it into pure icon buttons.

The tools in the tool shelf doesn't have a Python tool tip by design. This buttons sits on top of the normal operators, and doesn't access the tool tip of it.

Note: It is not recommended to turn the Python tool tips off.

## Developer Extras

This tick box turns on or off the developer entries in the right click menus.

## Sort Search by Most Recent

This affects all search fields in Bforartists. Sort the recently searched items at the top.

## Editors Panel

### Region Overlap

This checkbox will enable Blender to draw the Header, Tool Shelf and the Sidebar overlapping the 3D View. The transparent areas becomes workspace area. You can for example select vertices now in the transparent areas.

If you have a capable graphics card and drivers with *Triple Buffer* support, clicking the checkbox will enable the overlapping regions to be drawn using the *Triple Buffer* method, which will also enable them to be drawn using Alpha, showing the 3D View contents trough the *Object Tools* and *Transform Properties* regions.

### Navigation Controls

Show the navigation controls in the 2d and 3d views

## Color Picker Type

Choose the type of Color picker that will show when you click on a color field. You can choose between three square types and two circle types.

## Header Position

Define at which default position the headers of the editors should reside.

## Factor Display Type

Display factor values either as percentage or as factor.

## Temporary Editors subpanel

How the temporary editors behave.

### *Render in*

Where to display the rendered image.

### *File browser*

Where to open the file browser.

## Status Bar subpanel

What content to display in the status bar at the bottom. The items should be self explaining.

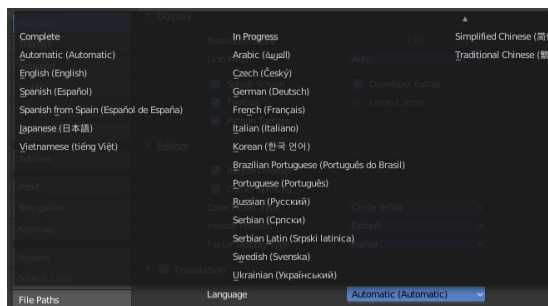

## Language Panel

Choose another default language for Bforartists.

## Language

Choose between automatic language detection. In this case the system language gets chosen. Or pick a language that you want to use.

## Translate

### Tool tips

Tool tips translates the tool tips too.

### Interface

Interface translates all the interface texts.

### Reports

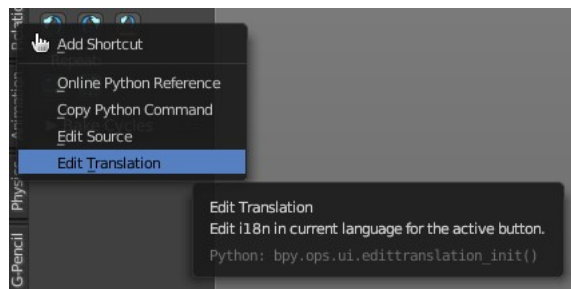

Translate report and error messages too.

### New Data

New data is meant to edit the localization texts.

This can be done in the right click menus of the tools when everything is set up in the correct way.

This is a development feature. You need a repository of Bforartists!

**Note**  
This feature is currently not functional in Bforartists. It ends in an error message.

Let's nevertheless document the way how it should work. Note that you need a Bforartists repository for that. The binary version does not come with the editable \*.po files, but with already compiled \*.mo files for the translation.

Note that you first need to set the path to the translation files for that. Or you will get an error. This is done in the File tab. The |18n string.

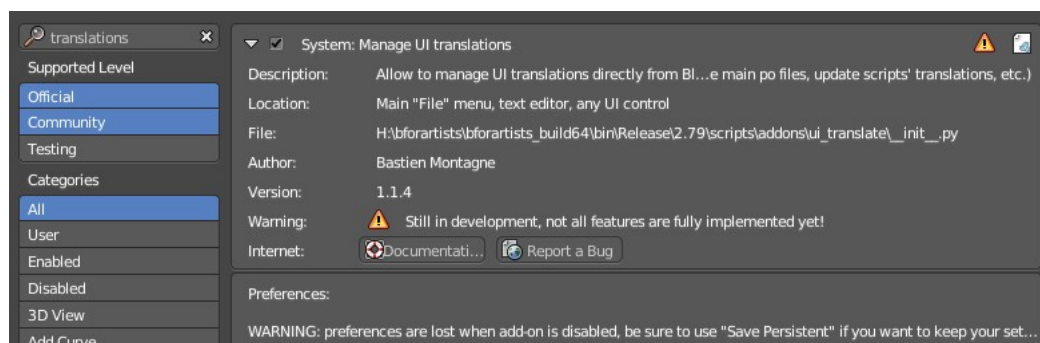

The path should lead to the \*.po files that you want to translate. Which can be found in the Bforartists repository.

And you need to enable the Manage UI translations add-on. And to fix the paths in this add-on. The default

paths are currently set for Blender.

And then you might end in this error here ...

In case somebody has an idea what's going on here, every hint is welcome ...

---

## Text Rendering Panel

Text related settings for the font of the interface.

### Anti Aliasing

Use Anti Alias at the UI elements to prevent pixelated look of the font.

### Hinting

What sharpening method to use to make the text render sharp.

### Interface Font

Define a custom interface font. The font in the whole UI.

### Monospace Font

Define a custom Monospace font. That's the one used in the python console for example.

---

## Menu Panel

### Open on Mouse Over

Normally you click at a menu to open it. With Open on Mouse Over the menu opens up when you just hover with the mouse over it.

#### ***Top Level***

Adjust the time delay before the top level menu opens on mouse over.

#### ***Sub Level***

Adjust the time delay before a sub level menu opens on mouse over.

### Pie Menus

Bforartists has some pie menus that can be called by hotkeys. Here you find some settings for it.

#### ***Animation Timeout***

The pie menu fades in with an animation. Adjust the time needed to fully unfold the pie menu.

#### ***Top Key Timeout***

Pie menu button longer held than this time will dismiss the menu on release.

#### ***Recenter Timeout***

Pie menus will use the initial mouse position as center for this amount of time. The value is in 1/100 seconds.

#### ***Radius***

The pie menu size in pixels.

#### ***Threshold***

The distance that is needed from the center to move the mouse so that a selection can be made.

#### ***Confirm Threshold***

Distance threshold after which selection is made. A value of zero disables this feature.

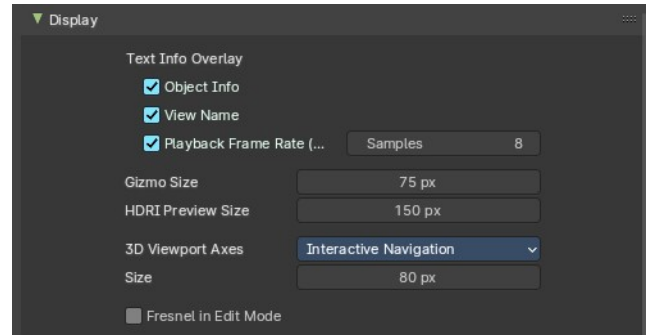

# Viewport

Contains the settings for the 3D Viewport.

## Display

## Text Info Overlay

### Object Info

Display current frame, collection name and Object name in the upper left edge of the 3D view.

The letters appears in yellow when the current frame of the selected object has a keyframe.

### View Name

Display the name of the current view up left in the 3D view.

### Playback Frame Rate (FPS)

Show the frames per second screen refresh rate while an animation is played back. It appears in the viewport corner, displaying red if the frame rate set cannot be reached. And replaces the View name while the animation is playing.

### Frame Rate Samples

The number of frames to use for calculating the fps average. A value of zero calculates the fps automatically, where the number of samples matches the target fps.

## Gizmo Size

Adjust the size of the transform gizmo that appears when you have one of the transform tools activated.

## HDR Preview size

How big the preview spheres are displayed.

## 3D Viewport Axis

Adjust the appearance of the 3D Viewport mini axis widget.

### Off

Hides the Mini axis widget

### Simple Axis

Shows simple axis. This widget type is not interactive. It just shows the state of the viewport rotation.

### Size

The size of the simple mini axis widget.

### Brightness

The brightness of the simple mini axis widget.

### Interactive Navigation

The default mini axis widget. This widget is interactive. Clicking and dragging will rotate the viewport. Clicking at one of the colored spots at the end of the axis will snap to the nearest orthographic view.

### Size

The size of the interactive navigation widget.

## Fresnel in Edit Mode

Enable a fresnel effect on edit mesh overlays. This feature improves shape readability of very dense meshes. But can increase eye fatigue when modeling lower poly.

---

## Quality

Contains the settings to adjust the display quality in the viewport.

## Viewport Anti-Aliasing

The anti alias quality settings for the solid mode rendering in the 3d viewport.

## Multi sampling

Set the OpenGL Multi sampling in case your system supports it.

## Grease Pencil Multi sampling

The grease pencil drawing has its own OpenGL Multi sampling. Set the OpenGL Multi sampling in case your system supports it.

## Edit Mode Smooth Wires

Enable Edit Mode edge smoothing which reduces anti alias and makes the edge more sharp. A change requires a restart of the software.

## Textures

### Limit Size

Limit the maximum resolution for pictures used in textured display to save memory. The limit options are specified in a square of pixels, (e.g.: the option 256 means a texture of 256×256 pixels) This is useful for game engineers, whereas the texture limit matches paging blocks of the textures in the target graphic card memory. Available Options are: *Off* (No limit), 128, 256, 512, 1024, 2048, 4096, and 8192.

### Anisotropic Filtering

Sets the level of anisotropic filtering. This improves the quality of how textures are drawn at the cost of performance. Available Options are: *Off* (No Filtering), 2x, 4x, 8x, and 16x.

### Clip Alpha

Clip alpha when the value is below the here defined value.

### Image Display Method

The method that is used to draw textures in the viewport.

## Selection

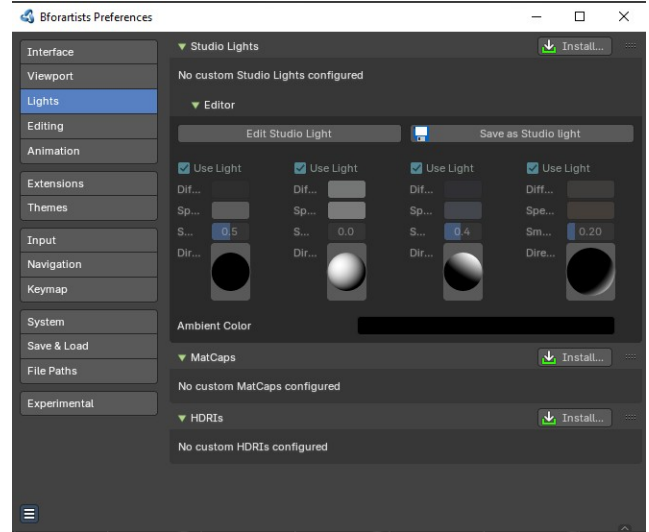

OpenGL Depth picking tries to pick the object in front. Without this method you may pick an object underneath.

# Lights

The viewport uses different light setups in different situations. You can switch between them in the shading drop down in the 3d view up right.

This tab allows you to customize these light setups. And install custom light setups.

## Studio Lights

The 3D view uses Solid OpenGL lamps to light the 3D view. You can enable four different light sources here. These lamps does not affect the rendering. Their only purpose is to light the 3D view.

You can turn on or off the lamps. But there should be at least one light enabled.

## Install

Install an external studio light.

## Preview Window

This window appears when you have a studio light saved, or a new studio light installed.

Down left you can see the name of the saved library. mystudio.sl .

This window gives you a preview of how this studio light looks like in the 3D view then.

Up right you can find two buttons.

## Delete Studio Light

Deletes the studio light.

## Copy Studio Light settings to the Studio Light Editor

The editor settings does not update immediately. It shows the default studio light setting. So when you want to edit the studio light, then you want to press this button to update the editor values first.

## Edit Studio Light

Enable the editing of the studio light setup.

## Save as Studio Light

Save the current light setup as a studio light setup. Note that this does not export the light, but saves its settings internally in the appdata directory.

## Use Light

Turn on or off this specific light.

## Diffuse

**Diffuse** color is the constant color of the lamp.

## Specular

**Specular** is the highlight color of the lamp.

## Smooth

Smooth the lighting from this specific light.

## Direction

Adjust the direction. Click into the field and drag the sphere around until you have your desired light setup.

---

## MatCaps

Matcaps is a special material that can be assigned quickly to preview geometry. Usually matcaps are used while sculpting. You can switch between them in the shading drop down in the 3d view up right.

Install and manage custom matcaps.

## LookDevHDRI's

You can light the scene with an environment image instead of lights. This is done with hdri images.

The viewport can do this in realtime when the shading is set to Viewport Shading.

Install and manage custom LookDev HDRI's. Basically every image could do the trick here. But the hdri's uses a special spherical

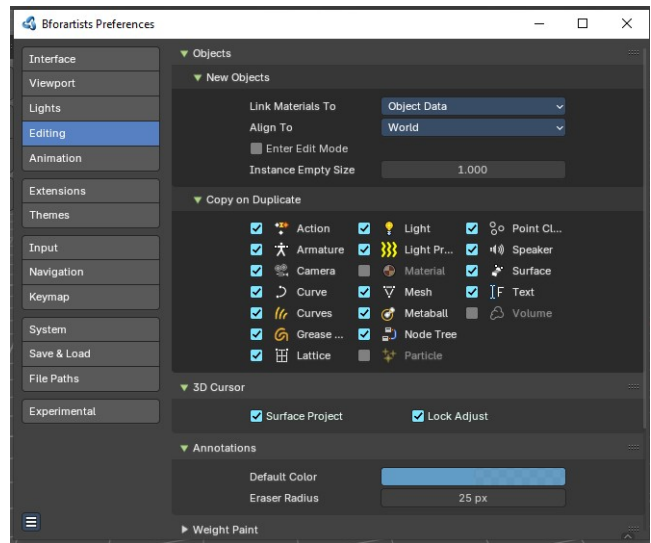

mapping. So you better use hdri images for this purpose.

# Editing

Contains the settings around editing. Objects, Data, etc.

## Objects

### New Objects

#### *Link Materials To*

Define how materials will be linked to its objects. Almost everything in Bforartists is organized in a hierarchy of data-blocks. A data-block can be thought of as containers for certain pieces of information. For example, the Object data-block contains information about the Object's location while the Object Data `ObData` data-block contains information about the mesh.

#### **ObData**

Any created material will be created as part of the ObData data-block.

#### **Object**

Any created material will be created as part of the Object data-block.

## Align To

### World

New objects align with world coordinates.

### View

New object align with view coordinates.

## Enter Edit Mode

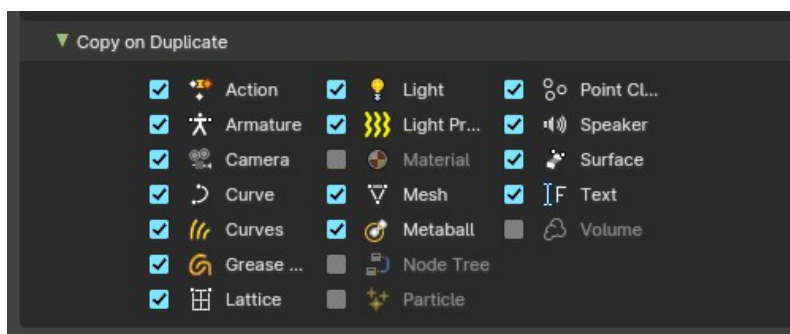

If selected, Edit Mode is automatically activated when you create a new object.

## Instance Empty Size

Increase or decrease the size of collection empties.

## Duplicate Data

When you duplicate data, then most or all its subpart gets duplicated too. Define which supports should be duplicated when you duplicate an object.

## 3D Cursor

### Cursor Surface Project

Use the surface depth to place the 3D cursor. That way you can place the 3D cursor at the surface of an object.

### Cursor Lock Adjust

Place the cursor without a jumping effect at the new location when lock to cursor is used.

## Annotations

### Default Color

The default color for the annotations pencil.

### Eraser radius

The eraser radius.

# Weight Paint

## Use Custom Colors

Bforartists uses by default a gradient that goes from red to green to blue to black to display the different weight at a mesh.

Setup a custom gradient for the colors of a weight paint.

**The + Button** adds a color stop point, which can be moved around. That way you can have more than one color in the gradient.

**The - Button** removes the currently selected color stop point.

## Tools Menu

**Flip Color ramp** flips the color ramp.

**Distribute Stops from Left** distributes the color stops from the left. The position at the right will remain empty.

**Distribute Stops evenly** distributes the color stops evenly across the gradient.

**Eyedropper** allows you to pick a color from the gradient.

**Reset color ramp** resets the color ramp to the default state.

**Color Mode** is a drop down box to choose the color mode for the gradient.

**Interpolation** is a drop down box to choose the interpolation mode for the gradient.

In the **Color Ramp element** you will see the color ramp with the single color stops.

**Choose Active Color Stop** is the stop point of the gradient.

**Position** is an edit box where you can numerically fine tune the position of the currently selected color stop.

**Color Ramp Element** displays the color of the current selected color stop. When you click at it then you can open a color picker to change the color of the current color stop.

### **Background Color**

Background color is the same color than the secondary color from the color picker. When you click at it then you can open a color picker to change the secondary color.

### **Gradient Stroke Mode**

Set the gradient stroke mode.

---

## **Grease Pencil**

### **Manhattan Distance**

The minimum number of pixels the mouse has to move horizontally or vertically before the movement is recorded.

### **Euclidean Distance**

The minimum distance that mouse has to travel before movement is recorded.

---

## **Text**

### **Auto-close Character Pairs**

Automatically close relevant character pairs when typing in the text editor.

---

## Node Editor

### Auto Offset

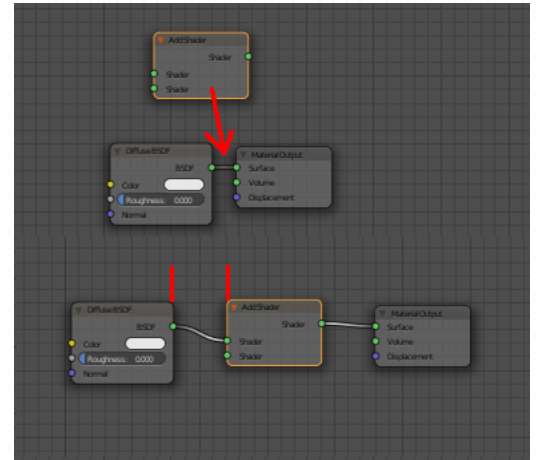

Use Auto Offset.

### Auto Offset Margin

Minimum distance in the node editor between nodes for auto offsetting.

When you insert a new node between two existing connected nodes, then the two nodes gets pushed to left and right, with an offset. Adjust this offset.

### Preview Resolution

Resolution used for shader node previews, which are displayed above the nodes.

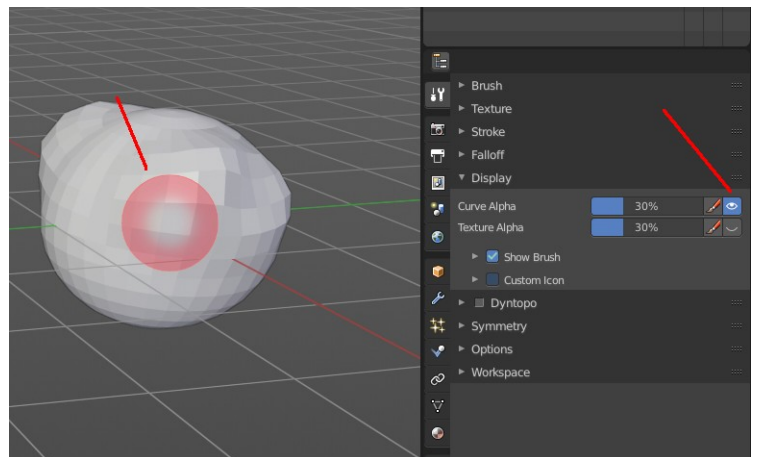

---

## Miscellaneous

### Sculpt Overlay Color

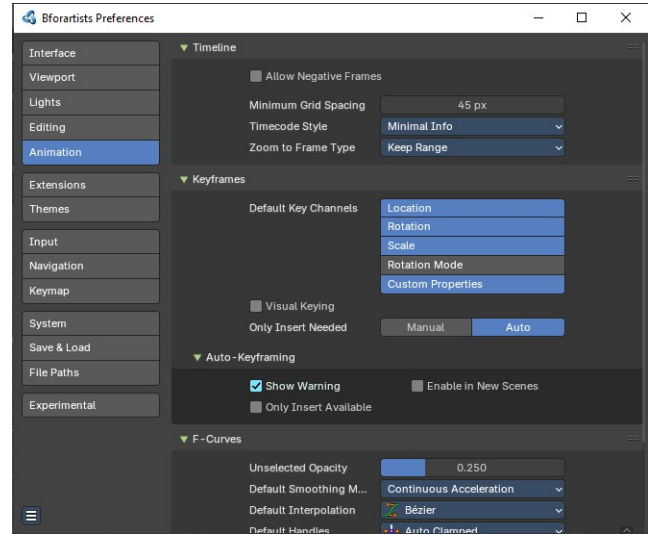

This color button allows the user to define a color to be used in the inner part of the brushes circle when in sculpt mode, and it is placed as an overlay to the brush, representing the focal point of the brush influence.

The overlay color is visible only when the overlay visibility is selected (clicking at the eye to set its visibility), and the transparency of the overlay is controlled by the alpha slider located at the brush pop-up, located at the top of the tool shelf, when in sculpt mode.

# Animation

Contains the settings for the animation editors.

## Timeline

### Allow negative Frames

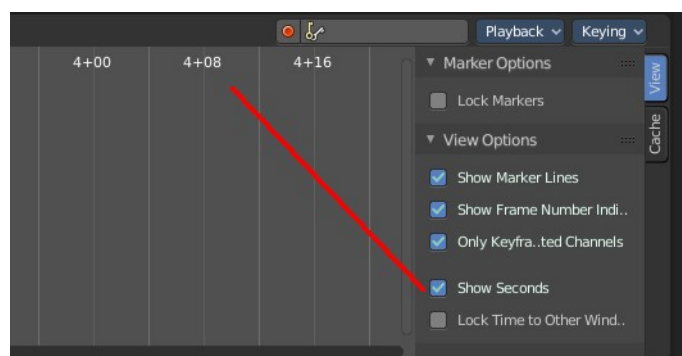

### Minimum Grid Spacing

Adjust the minimum number of pixels between grid lines in a 2D viewport. This affects for example Timeline, Dope sheet, Graph or NLE Editor.

### Time Code Style

In Timeline, Dope sheet, Graph and NLE editor you can either display the keyframe number or the time in the timeline. Define how the time gets displayed when you have chosen to display time.

### Zoom To Frame Type

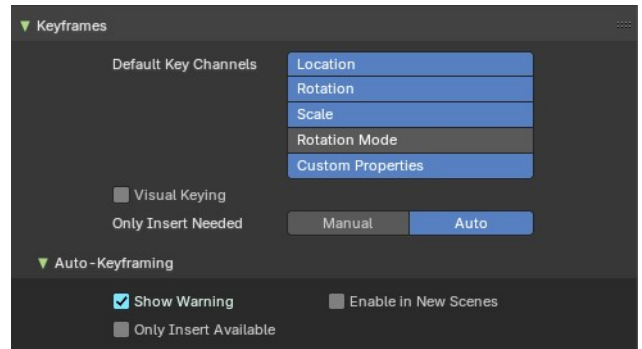

Timeline, Dope sheet, Graph and NLE. Define how zooming to frame focuses around current frame.

## Keyframes

### Default Key channels

Define which channels are recorded by default In case no keyingset is defined.

### Visual Keying

When an object is using constraints, the objects property value doesn't actually change. *Visual Keying* will add keyframes to the object property, with a value based on the visual transformation from the constraint.

### Only Insert Needed

With Auto it will only insert keyframes if the value of the property is different.

If there is a keyframe on the current frame, and it has no changes, it will skip recording over the keyframe.

If there is no keyframe, and it has no changes, skip recording the keyframe.

### Auto Keyframing subpanel

#### Show Warning

Displays a warning at the top right of the *3D View*, when moving objects, if *Auto Keyframe* is on.

#### Only Insert Available

This will only add keyframes to channel F-Curves that already exist.

#### Enable in new scenes

Automatic keyframe insertion for objects and bones as Default setting for new scenes.

## F-Curves

### Unselected Opacity

The amount that unselected F-curves stands out from the background in the Graph Editor.

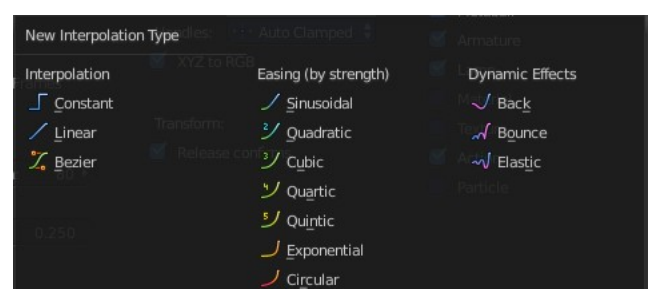

### Default Smoothing Mode

Auto handle smoothing mode for new added curves. None or Continuous acceleration.

### Default Interpolation

This controls how the state between two keyframes is computed. Default interpolation for new keyframes is Bezier which provides smooth acceleration and de-acceleration whereas Linear or Constant is more abrupt.

## Default Handles

The default handle types for F-Curves.

## XYZ to RGB

Color for X, Y or Z animation curves (location, scale or rotation) are the same as the color for the X, Y and Z axis.

## Channel Group Colors

Use animation channel group colors. Uses the bone group colors.

## Only Show Selected F-Curve Keyframes

Just show the keyframes from the selected curves only.

## F-Curve High Quality Drawing

Display the curves in highest quality.

# Extensions

In this section you can manage the add-ons and themes.

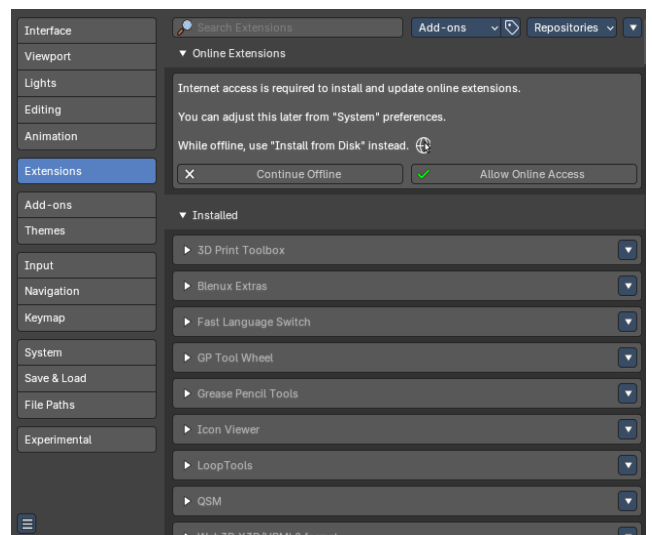

An extension add-on is external software written by other developers. Add-ons are a way to extend the core functionality of Bforartists. Bforartists already comes with lots of extensions add-ons. Some already activated. Here you can manage them, and add even more extension add-ons if required.

**Note:** All Blender addons are compatible with Bforartists.

A theme allows you to customize the colors of the user interface.

Some addons and themes are included. Some addons and themes can now be downloaded externally when you opt-in to Allow Online Access.

**Note:** Bforartists comes with some add-ons that are required by Bforartists to work properly. You will see a warning in those addons. Don't turn them off. If off, vital

parts of Bforartists will not longer work, ei the toolbar settings.

## Use

### Drag and Drop

You can drag any extension zip file from the internet or from the computer into Bforartists from the operating system expolorer. This will automatically install and activate the addon or theme extension.

### Install from the internet

To install extensions from the internet, internet access is required. You can adjust this later from the “System” preferences in the Network panel. Once you have allowed online access, you will access the default Blender extensions website with free addons and themes.

### Install from Disk

You can optionally also install addons and extensions from a disk location using the install from disk operators.

## Header

### Searchfield

Search for specific addons.

### Filter by Type

Choose what extension type to display.

Extensions are made of two types. Themes and add-ons.

### Extensions Filter

Filter the addons by type.

### Show only

#### Enabled Extensions

Show just the enabled extensions.

#### Updates Available

Show just the extensions where an update is available.

#### Installed Extensions

Show all installed extensions.

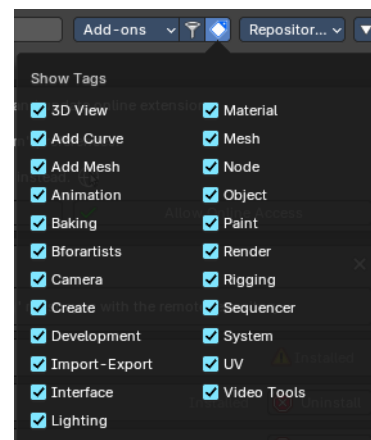

## Show

### Legacy Add-ons

Show legacy addons.

### Show Tags

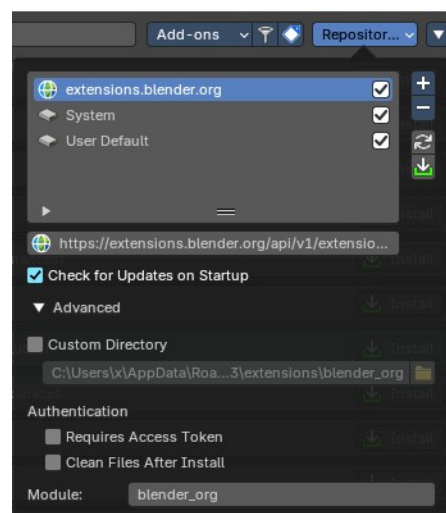

Filter the addons further by tags.

## Repository

Manage the extension repositories.

Extensions are managed in so called repositories. A place where the addons are stored. This includes the online sources, but also where the addons are stored at your local installation.

### Repository List

The list of currently available repositories.

extensions.blender.org is the official extension repository from Blender, which we rely at. It is online.

User Default is the offline default repository. This includes the core addons and the addons that you have installed.

### Enable

Enable the repository.

### URL field

In case the selected repository is an online source you will see the URL property to this repository. You can also

edit this URL here.

### Check for Updates on Startup

In case the selected repository is an online source you will see the Check for Updates on Startup properties to this repository.

When ticked, checks for available updates. And notifies you about it in the list of extensions then. You can also turn on the Extensions Updates notification in the footer.

### Add

Add a repository.

### Add Remote Repository

Add a repository from an online source. It should ideally contain extensions. A dialog will pop up.

### Add New Extension Repository dialog

#### URL

The url for the online repository

#### Check for Updates on Startup

Check if updates are available.

#### Authentication

For addons that requires an authentication.

#### Requires Access Token

Enable Requires Access Token.

#### Secret

The secret password for the authentication.

#### Use Custom Directory

Use a custom install directory. By default it installs in \AppData\Roaming\Bforartists\Bforartists\VERSIONNUMBER\scripts\addons

VERSIONNUMBER stands for the Blender version number here.

Note that the custom directory needs still to be in the \AppData\Roaming\Bforartists\Bforartists\VERSIONNUMBER\ path.

#### Custom Directory

The custom directory that you want to use.

### **Create**

Create the new repository.

### **Cancel**

Cancel.

### **Add Local Repository**

Add a local repository.

### **Name**

The name of the repository

### **Use Custom Directory**

Use a custom install directory. By default it installs in `\AppData\Roaming\Bforartists\Bforartists\VERSIONNUMBER\scripts\addons`

VERSIONNUMBER stands for the Blender version number here.

Note that the custom directory needs still to be in the `\AppData\Roaming\Bforartists\Bforartists\VERSIONNUMBER\` path.

### **Custom Directory**

The custom directory that you want to use.

### **Create**

Create the new repository.

### **Cancel**

Cancel.

### **Remove**

Remove the chosen repository.

### **Remove Repository**

Removes the repository from the repository list. But keeps the files locally.

### **Remove Repository & Files**

Removes the repository from the repository list. And removes the local files too.

### **Check for Updates**

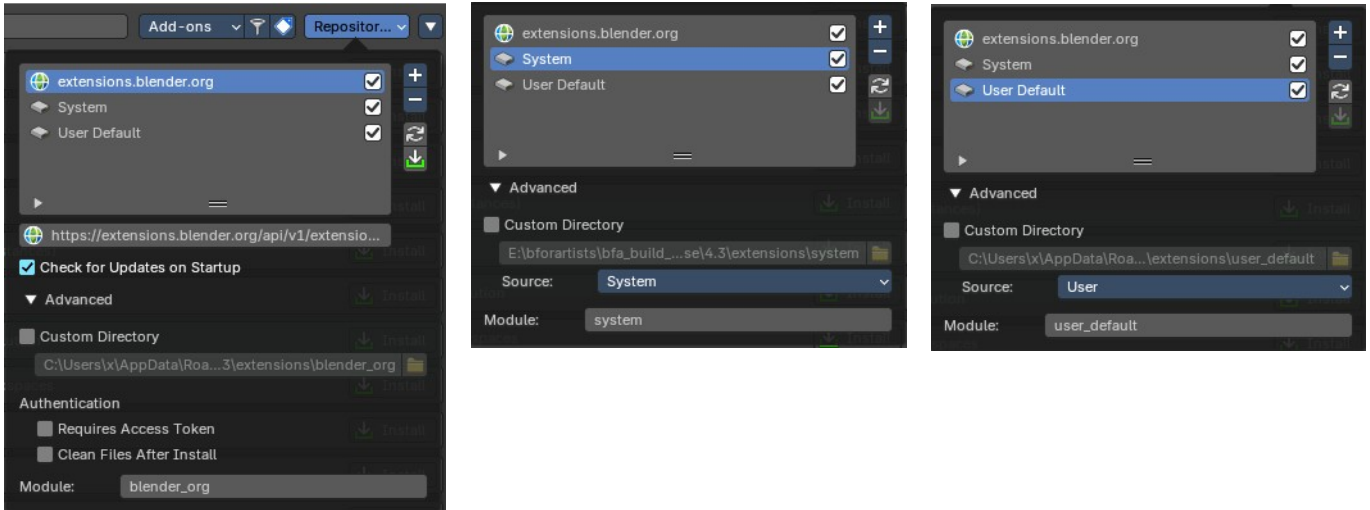

Check if updates for extensions are available. Note that this feature requires to allow online access. Also note that this feature works at the selected repository only

## Install Available Updates

Install all available updates. Note that this feature requires to allow online access. Also note that this feature works at the selected repository only

## Advanced Subpanel

Adjust settings for the repositories.

## Custom Directory

Use a custom install directory. By default it installs in \AppData\Roaming\Bforartists\Bforartists\VERSIONNUMBER\scripts\addons

VERSIONNUMBER stands for the Blender version number here.

Note that the custom directory needs still to be in the \AppData\Roaming\Bforartists\Bforartists\VERSIONNUMBER\ path.

## Directory

The custom directory that you want to use.

## Browse

Browse for the directory that you want to use

## Source

Select if the repository is a system directory, or a user directory. Normally this updates automatically when you use a system or a user directory in the list above. But here you can customize it.

## Authentication

For addons that requires an authentication.

## Requires Access Token

Enable Requires Access Token.

## Secret

The secret password for the authentication.

## Module

The unique module identifier. It identifies the repositories.

## Extensions Settings

### Refresh Remote

Check if updates for extensions are available for the online extensions. Note that this feature requires to allow online access. Also note that this feature works on ALL repositories.

### Refresh Local

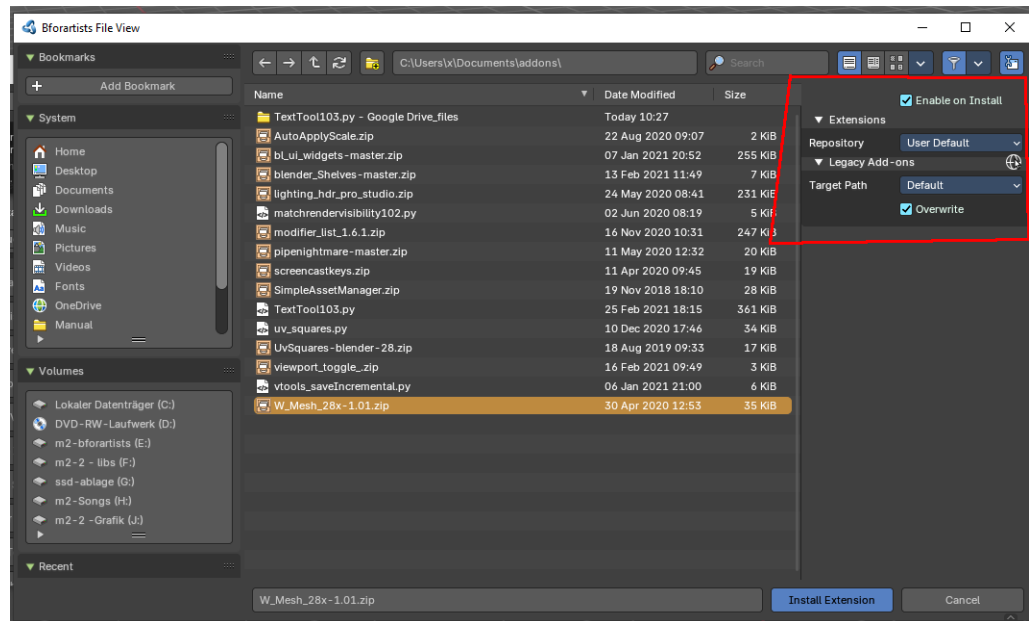

Refresh local extensions to apply changes. Note that this feature works on ALL repositories.

### Install Available Updates

Install all available updates. Note that this feature requires to allow online access. Also note that this feature works on ALL repositories.

### Install from Disk

Install an addon from disk. Opens a dialog where you can choose a local addon to install. At the left you can see some further settings. They should be self explaining.

## Online Extensions Tab

This tab shows as long as you haven't allowed or declined the online access for the addons.

## Continue Offline

Disallow online access. You will work offline.

## Allow Online Access

Allow online access. Now you can download and activate extensions from online repositories. And you will get notifications if updates are available.

Note that you can change your choice afterwards in the System preferences.

Note also that you can of course also install extensions from disk when you are online.

## Repository Access Errors

In case you have added an invalid online repository you might be faced with a warning. You might want to fix the invalid extension repository then.

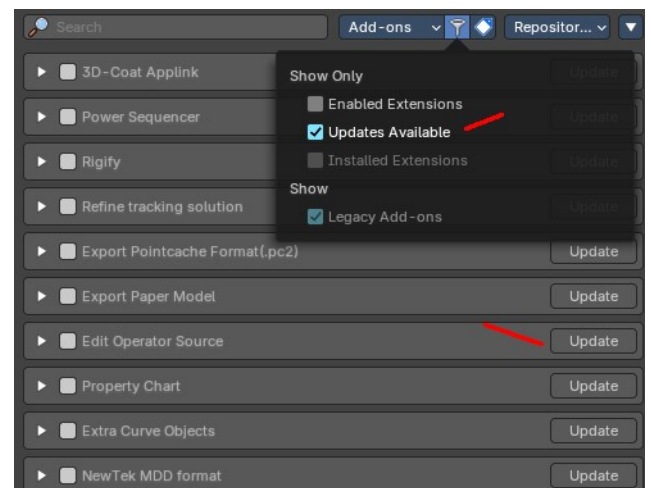

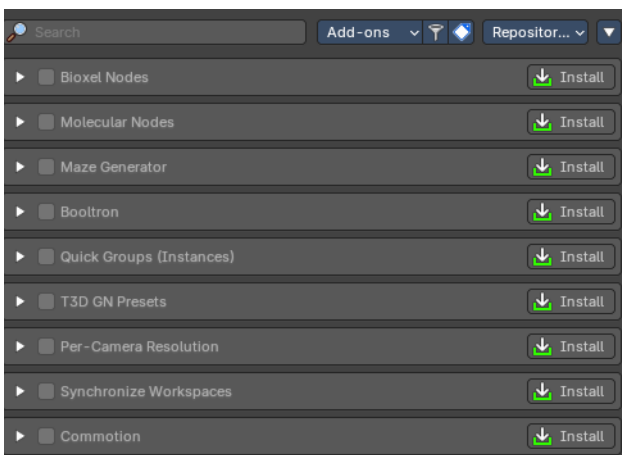

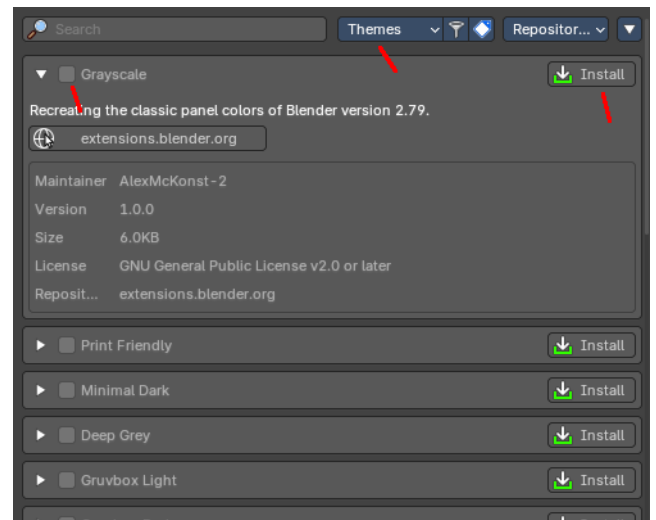

**Note:** Bforartists doesn't host extensions. This URL was just added for demonstration purposes.

## Extensions List

The actual list of installed or available extensions. Themes and add-ons.

Each addon can be enabled or disabled. At the right you will find an install or update or remove button. Dependant of the state of the addon. And when you open the extension tab then you will find further informations and settings.

Some addons have a category label, which can be found at the left. Core, Edit, Mesh, etc. . Be careful not to disable the extensions that are labeled as Core and wears a warning sign. They are required by Bforartists to work proper.

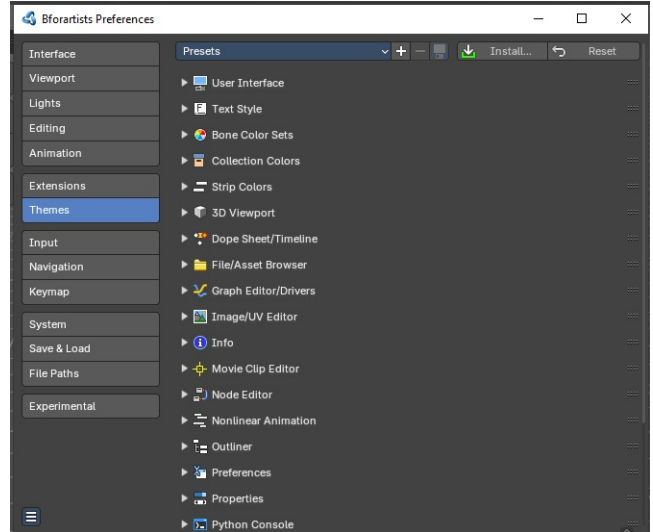

# Themes

The Themes tab allows you to customize interface appearance and colors. There are various elements that can be themed.

Any change here will appear in real-time on your screen in the corresponding editor.

To change a color for a UI element, simply click at one of the color fields. A color dialog will open up to choose a new color.

## Presets

Bforartists comes with several theme presets. You can choose between them in the drop down box. Don't forget to save the user settings to make the change to the new preset permanent.

## Create new Theme

To create a new theme, click the + button next to the preset selection drop-down and enter a name. This will save the theme to an XML file in the `./scripts/presets/interface_theme/` sub directory of one of the configuration directories.

To share the new created theme you have to copy it from that folder. This XML file can then be loaded as a theme at another computer with Bforartists installed.

## Remove Theme

To remove a custom theme, click the - button next

## Save Theme

To save changes to a custom theme, click on the save icon.

## Install

Install an external theme. This button will open a file browser.

## Reset

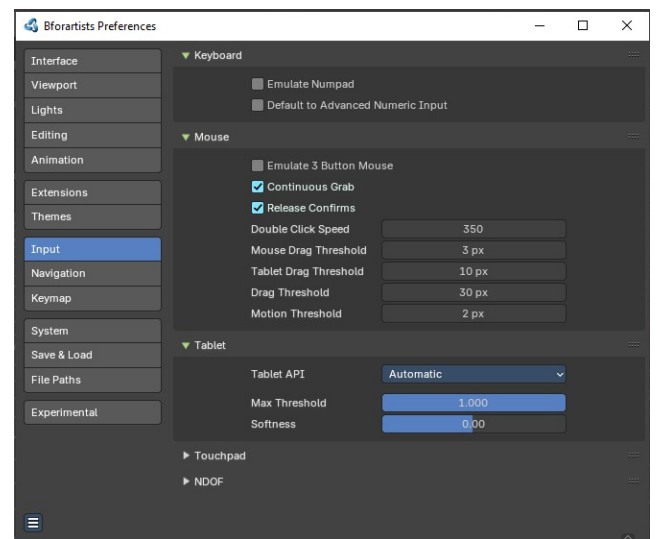

Resets all made changes, and resets the current theme to its initial state.

## List of Editors

The list of the editors that you can theme. Every editor can have its own theming.

# Input

This tab contains some input related settings.

## Keyboard

### Emulate Numpad

Laptops usually doesn't have Numpad keys. Choose to use the number keys above the letters as Numpad keys.

### Default to advanced numeric input

When entering numbers while transforming default to advanced mode for full math expression evaluation.

## Mouse

### Emulate 3 Button Mouse

In the Windows world 3 button mouses are common. But Apple for example has a single mouse button. Bforartists can emulate a 3 button mouse. The third mouse button

will then be emulated by a key combination.

3-button Mouse	2-button Mouse	Apple Mouse
LMB	LMB	LMB (mouse button)
MMB	Alt - LMB	Alt - LMB (Option/Alt key + mouse button)
RMB	RMB	Cmd - LMB (Command/Apple key + mouse button)

Mouse/Keyboard combinations referenced in this manual can be expressed with the combinations shown in the table. For example, MMB drag becomes Alt - LMB drag. Shift - Alt - RMB becomes Shift - Alt - Cmd - LMB on a single-button mouse.

## Tablet

This panel contains some tablet related settings.

### Tablet API

Choose which API Bforartists should choose for the pressure sensitivity of your tablet.

### Max Threshold

The raw input pressure value which is interpreted as 100 % by Bforartists.

### Softness

Adjust the pressure softness of the low pressure response onset using a gamma curve.

## Touchpad

### Multi Touch Gestures

Use multi touch gestures for navigation with touchpad instead of scroll wheel emulation.

## NDOF

You can use a 3D mouse in Bforartists. Here you find some 3D mouse related settings.

### ***Pan Sensitivity***

Adjust the pan sensitivity.

### ***Orbit Sensitivity***

Adjust the orbit sensitivity

### ***Deadzone***

The initial movement that is needed before the movement gets recognized.

### ***Navigation***

Choose the navigation style between Free and Orbit.

### ***Rotation***

Adjust in what style you rotate the 3D View. Turntable and Trackball navigation reacts a bit different. Turntable navigation tries to hold the horizon line while rotation. Turntable rotation rotates also the horizon line.

### ***Show Navigation Guide***

Display the axis and center during rotation.

### ***Invert Zoom***

Zoom using opposite direction.

### ***Lock Camera Pan/Zoom***

Pan / Zoom the camera view instead of leaving the camera view when orbiting.

### ***Pan Swap Y and X Axes***

Pan uses up - down instead of forward - backward

### ***Invert Axis Pan***

The invert axis for panning. Inactive axis are not inverted.

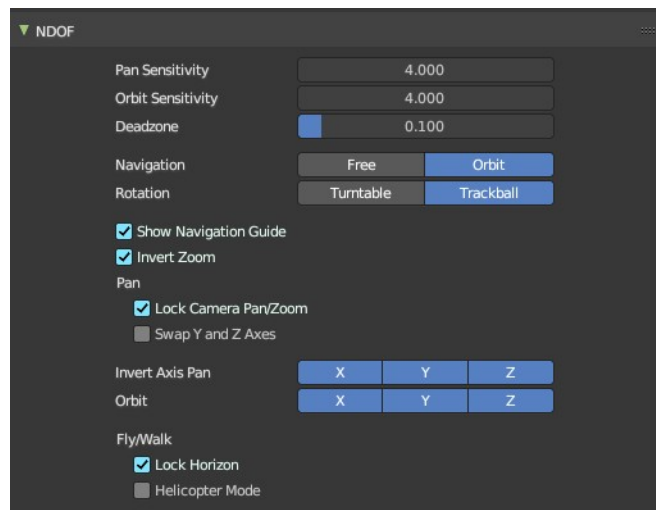

### ***Orbit***

The axis to orbit around when panning.

### ***Fly / Walk***

### ***Lock Horizon***

Keep horizon level while flying with 3D mouse.

## Helicopter Mode

Using up/down directly controls the Z position in the 3D viewport.

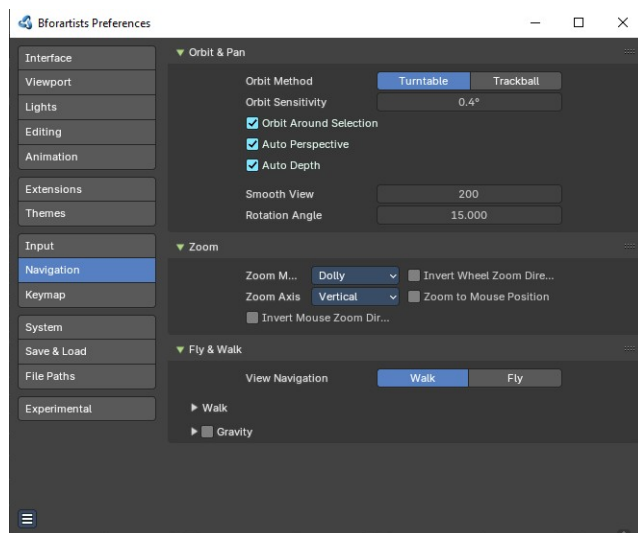

# Navigation

The navigation section contains the settings for navigating in the 3D view.

## Orbit & Pan

### Orbit Method

Adjust in what style you rotate the 3D View. Turntable and Trackball navigation reacts a bit different. Turntable navigation tries to hold the horizon line while rotation. Turntable rotation rotates also the horizon line.

### Orbit around selection

The selected object becomes the rotation center of the viewport. When there is no selection the point of the last selection will be used.

### Auto Perspective

With Auto perspective off when you switch to one of the side views, then the chosen orthographic or perspective view is kept. Means when you have the distorted perspective view, and switch to top view, then your mesh will be perspective distorted here too.

With Auto Perspective the view in the side views will be orthographic, and not perspective, no matter what View Persp/Ortho is chosen.

### Auto Depth

Use the depth under the mouse to improve view pan, rotate, zoom functionality.

### Smooth View

The switch to change to another view is animated. Adjust the length of time the animation takes when changing the view with the Numpad (Top/Side/Front/Camera...). A value of zero will remove the animation, and immediately switch to the chosen view.

### Rotation Angle

Rotation step size in degrees, when Numpad4, Numpad6, Numpad8, or Numpad2 are used to rotate the 3D View.

## Zoom

### Zoom Method

Adjust the zoom style.

#### ***Continue***

The *Continue* zooming option allows you to control the speed (and not the value) of zooming by moving away from the initial click point. Moving up from the initial click-point or to the right will zoom out, moving down or to the left will zoom in. The further away you move, the faster the zoom movement will be.

#### ***Dolly***

*Dolly* zooming works similarly to *Continue* zooming except that zoom speed is constant.

#### ***Scale***

*Scale* zooming depends on where you first click in the view.

### Zoom Axis

With Vertical moving up zooms out and moving down zooms in. With Horizontal moving left zooms in and moving right zooms out.

### Invert Mouse Zoom Direction

Inverts the Zoom direction for Dolly and Continue zooming.

### Invert Wheel Zoom Direction

Inverts the direction of the mouse wheel zoom.

### ***Zoom to Mouse Position***

When enabled, the mouse pointer position becomes the focus point of zooming instead of the 2D window center.

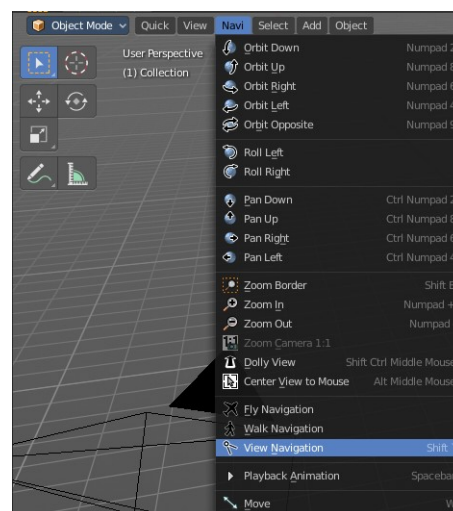

## Fly & Walk

Fly and walk are special navigation modes. They can be found in the Navi menu. The Fly & walk section also contains some settings from the View navigation style, since this style uses elements from walk and fly navigation too.

## View Navigation

Adjust how the View navigation in the 3D view behaves. You can choose between walk and fly.

## Walk

### Reverse Mouse

Reverse the mouse movement when you move upwards or downwards

### Mouse Sensitivity

Adjust how strong the viewport movement reacts to the mouse movement

### Teleport Duration

Adjust the teleport duration when teleporting in navigation mode.

### Walk Speed

Adjust the walk speed

### Speed Factor

Adjust the run speed.

## Gravity

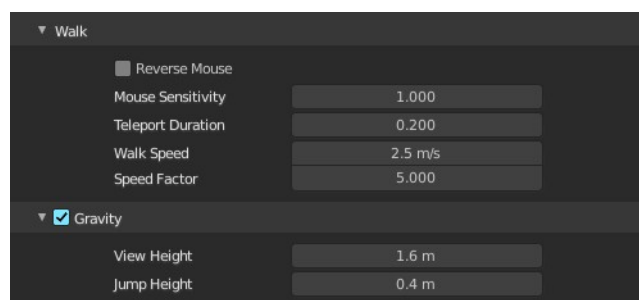

Choose if the virtual character, your point of view, uses gravity.

### View Height

Adjust the height of the point of view for your virtual character. This setting requires to have Gravity on.

### Jump Height

Adjust the maximal jump height for your virtual character. This setting requires to have Gravity on.

## Fly

Fly has no further settings.

# Keymap

The key map allows you to customize how Bforartists reacts to mouse and keyboard, and change key map entries. All Input behavior is defined in the key map.

## Header

## Key Configs

A drop down menu to choose existing key maps. The + button at the right adds a new key map. The current configuration will then be saved as a new key map.

## Import

Import an external key map. This opens up a file selector to choose the python file.

## Export

Export a key configuration python file from Bforartists.

## Filter Type

Define if you want to search for a tool name or for a hotkey. By tool name, or by the hotkey name

## Search Field

Enter a search string.

## Key map Editor

The Key map editor is the list where the single inputs are defined. Every input can have several specific operator settings in the lower area. The upper area defines the general things like the key combos. The lower area those operator

specific settings.

Normally you don't edit those key entries manually. Most of the usual tools have an entry in the right click menu to create or to change the hotkey. But sometimes you have to do this task manually.

### Map Type

Here you define what input will control the function.

### Type of Event

Here you define your main hotkey. In our case the right mouse.

### Operator

The Python operator name for the tool.

### Type of Event

The main hotkey again. For special events like mouse events you have a drop down box here.

### Value

What key action is required. On click, on double click, etc. ...

### Secondary hotkeys

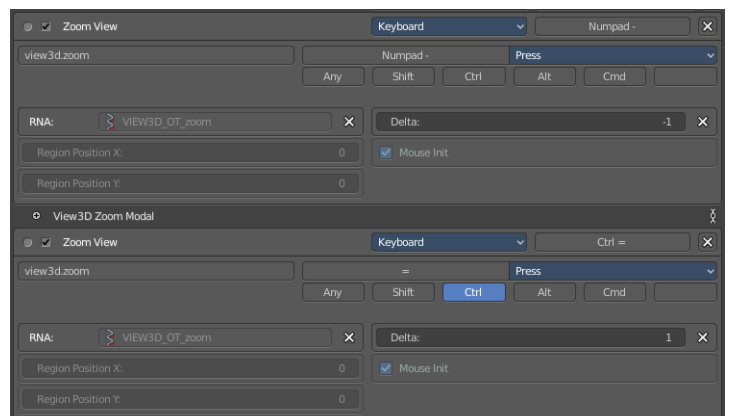

Many hotkeys uses a key combination, for example Shift D for select. Define those secondary hotkeys.

### Specific settings

Every operator can have several settings. And some tools even just defines itself by those different settings. Here you can see two different zoom view operators. They just differ in the Delta value.

What is equal in the key map in all cases is the RNA entry. That's the name of the operator again. But this time not the Python code operator name. But the C

code operator name.

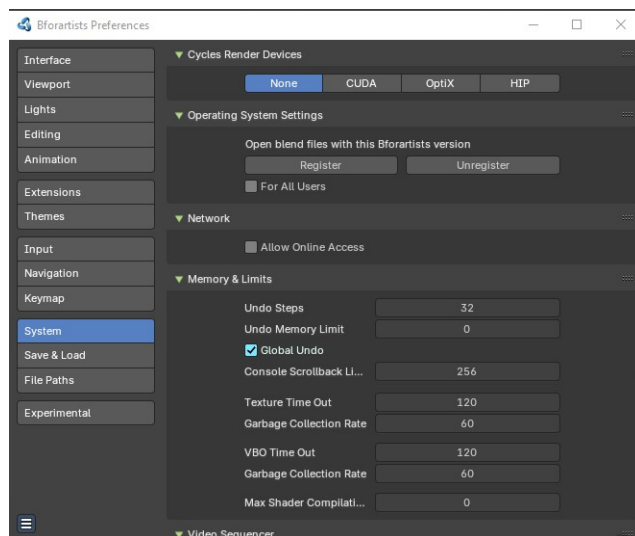

## Restore

When you modify a key map item, then you will see a Restore button appear at the right side. This indicates that this key map item got modified. A click at the Restore button will restore the original hotkey.

## System

The system tab contains system relevant settings. Such as Cuda for Cycles renderer or OpenCL or Memory related settings.

## Cycles Render Devices

The Options here will set the compute device used by the Cycles render engine.

### **None**

When set to *None* or the only option is *None*: your CPU will be used as a computing device for Cycles Render Engine.

### **CUDA**

If the system has a compatible Nvidia CUDA enabled graphics card you will be able to use it to render with the Cycles render engine.

### **OptiX**

Optix is a raytracing framework from Nvidia that runs on the GPU.

### **HIP**

If the system has a compatible HIP device, it will show up has an option for rendering cycles.

## OneAPI

If the system has a compatible oneAPI device, it will show up has an option for rendering cycles.

## Metal (Mac-OS only)

If the system has a M1/M2 chip, users can use the Metal back-end for rendering in cycles.

## Operating System Settings

Windows only.

Register or unregister to connect the blend file with this Bforartists version.

## For all Users

Register the file association for all users, or just for the current user.

## Make default

Associates the .blend file with this installation of Bforartists. This means that double clicking at a .blend file will now open this file with the currently open Bforartists installation. This is useful when you work with different versions of Bforartists, and want to open the files with an older or newer version.

## Network

Allow or disallow Online Access.

Online access is required to install extensions from external online repositories, and to update them.

## Allow Online Access

Allow internet access. Bforartists may access configured online extension repositories. Installed third party add-ons may access the internet for their own functionality.

## Time Out

The time in seconds to wait for online operations before a connection may fail with a time-out error. Zero uses the system defaults.

## Connection Limit

Limit the number of simultaneous internet connections online operations may make at once. Zero disables the limit.

## Memory and Limits

### Undo Steps

Number of Undo steps available.

### Undo Memory Limit

Maximum memory usage in Mb (0 is unlimited).

### Global Undo

Bforartists Undo system is split in several subpart. Global undo stores the undo step outside of Edit mode. For example for duplicating Objects, changing panel settings or switching between modes.

### Console Scrollback Lines

Maximum number of lines to store for the console buffer.

### Texture Time Out

Time since last access of a GL texture in seconds, after which it is freed. Set to 0 to keep textures allocated. Minimum: 0, Maximum: 3600.

### Garbage Collection Rate

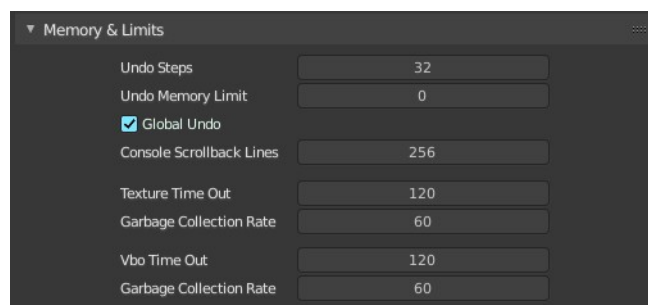

Number of seconds between each run of the GL texture garbage collector. Minimum: 0, Maximum: 3600.

### VBO Time Out

Time since last access of a GL Vertex buffer object, in short VBO, in seconds after which it is freed. Set to 0 to keep VBO allocated.

### Garbage Collection Rate

Number of seconds between each run of the GL vertex buffer garbage collector. Minimum: 0, Maximum: 3600.

## Video Sequencer

### Memory Cache Limit

Upper limit of the sequence's memory cache (megabytes). For optimum clip editor and sequencer performance, high values are recommended.

### Use Disk Cache

Store cached images to disk.

## Directory

The disk cache directory.

## Cache Limit

The disk cache limit in gigabytes.

## Compression

What compression method to use. Note that compression saves space, but costs performance.

## Proxy Setup

Proxies are preview objects, reduced in size to make a smooth working possible. Images for example.

## Automatic

Automatically create proxies for each image material.

## Manual

You have to create the proxies by hand.

## Sound

### Audio Device

Set the audio device.

### OpenAL

Provides buffered sound rendering with 3D/spatial support.

### OpenAL - OpenAL Soft

Provides buffered sound rendering with 3D/spatial support.

### SDL

Uses Simple Direct Media Layer API from libsdl.org to render sounds directly to the sound device output.

### Null

No Audio support. No audio output, but audio strips can be loaded normally.

## Channels

Set the audio channel count. Available options are: Mono, Stereo, 4 Channels , 5.1 Surround , 7.1 Surround

## Mixing Buffer

Set the number of samples used by the audio mixing buffer. Available options are: 512 , 1024 , 2048, 4096 , 8192, 16384, and 32768

## Sample Rate

Set the audio sample rate. Available options are: 44.1 Khz, 48 Khs, 96 Khz and 192Khz

## Sample Format

Set the audio sample format. Available options are: 32 bit float, 8 bit Unsigned, 16 Bits Signed, 24 Bits Signed, 32 Bits Signed, 32 Bits Float, and 64 Bits Float.

# Save & Load

## Blend Files

Blend file related settings. What happens at load, what happens at save ...

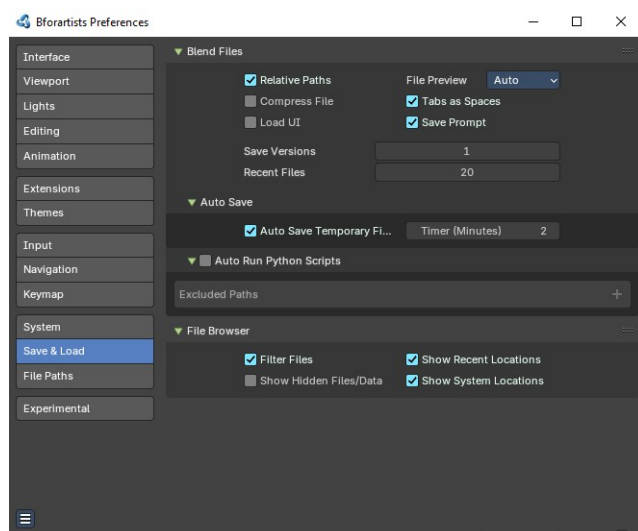

## Relative Paths

By default, external files use a relative path.

## Compress File

Compress blend-file when saving.

The option to Compress files will compact your files

whenever Blender is saving them. Dense meshes, large packed textures or lots of elements in your scene will result in a large blend being created.

This option may slow down Blender when you quit, or under normal operation when Blender is saving your backup files. Using this option traces processor time for file-size.

## Load UI

In Bforartists you can load the scene in the screen layout in which you have saved it. Default is off.

This can also be changed individually when loading a file from the *Open blend-file* panel of the File Browser.

## File Preview

### *None*

When this option is off, previews of images and materials in the File Browser are created on demand.

### *Auto*

Automatically create previews of images and materials in the File Browser. The best preview type is chosen automatically.

### *Screenshot*

Capture the entire window to create previews of images and materials in the File Browser.

### *Camera Preview*

Use a workbench render to create the previews of images and materials in the File Browser.

## Tabs as Spaces

For text files, automatically convert tabs into spaces when loading a blend file that contains a text file. Correct indentation is relevant for python scripts.

## Save Prompt

Ask for confirmation when quitting with unsaved changes.

## Save Versions

Number of versions created for the same file (for backup).

This option tells Bforartists to keep the indicated number of saved versions of your file in your current working directory when you manually save a file. These files will have the extension: `.blend1`, `.blend2`, etc., with the number increasing to the number of versions you specify. Older files will be named with a higher number. e.g. With the default setting of 2, you will have three versions of your file: `*.blend` (your last save), `*.blend1` (your second last save) and `*.blend2` (your third last save).

## Recent Files

The number of recent files to display in the Recent panel.

---

## Auto Save

### Auto Save Temporary File

Enable Auto Save. Auto save creates a temporary file.

Checking this box tells Blender to automatically save a backup copy of your work-in-progress to the Temp directory (refer to the File tab in the Preferences for its location).

The Auto Saved files are named using a random number and have a blend extension.

### Timer

Adjust the number of minutes between each Auto Save. The minimum is 1, and the Maximum is 60 (Save at every one hour).

---

## Auto Run Python Scripts

Run the python scripts at loading a blend file that includes these scripts.

### Excluded paths

Define file paths where loaded blend files should not run the included scripts even when auto run python scripts is ticked.

---

## File Browser

File browser related settings.

### Filter Files

By activating this, the file dialog in the File Browser will only show appropriate files in the Load dialog. Blend files for example.

The selection of file types can also be changed in the header of the file dialog.

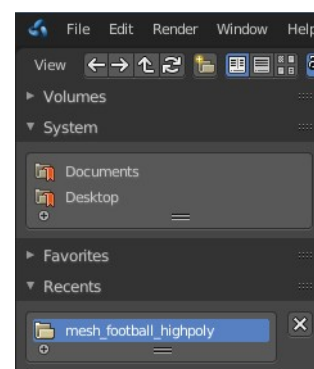

### Show Hidden File/Data

On non Windows systems like Linux and Mac OS X files are hidden by a dot in front of the file name. Here you can make them visible in the file browser if you want. Note that this feature does not work with Windows.

### Show Recent Locations

Hides the *Recent* panel of the File Browser which displays recently accessed

folders.

## Show System Bookmarks

Hides the System Bookmarks panel of the File Browser which displays the system bookmarks.

# File Paths

Contains everything file path related.

## Data

### Fonts

Default location when searching for font files.

### Textures

Default location when searching for image textures.

### Sounds

Default location when searching for sound files.

### Temporary Files

The location where temporary files are stored.

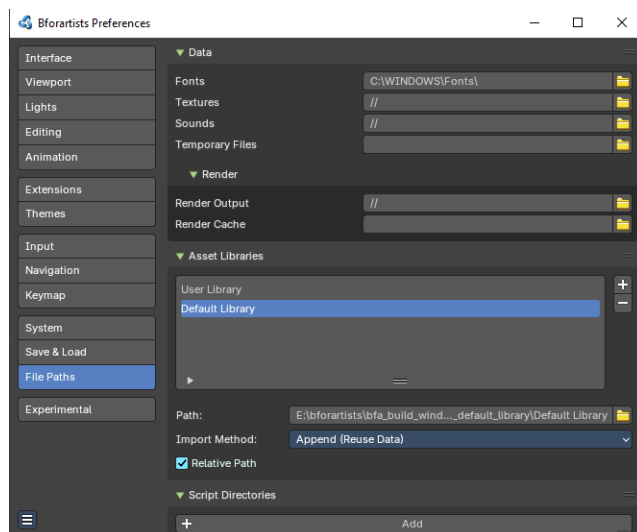

## Script Directories

An additional location to search for Python scripts.

By default Bforartists looks in several directories (OS dependent) for scripts. Here you can add another directory to check for scripts. This can be used to store certain scripts/templates/presets independently of the currently used Blender Version.

Inside the specified folder specific folders have to be created to tell Bforartists what to look for where. This folder structure has to mirror the structure of the scripts folder found in the installation directory of :

- scripts
- add-ons
- modules
- presets
- camera
- cloth
- interface\_theme
- operator

- render
- ...
- startup
- templates

Not all of the folders have to be present.

Python scripts (including driver expressions) are not executed by default for security reasons.

## Render

### Render Output

Where rendered images/videos are saved.

### Render Cache

The location where cached render images are stored.

## Applications

### Image Editor

The path to an external image editing software to use for image editing. Photoshop, Gimp, etc.

### Animation Player

By default Bforartists uses the internal player to play back animations. Choose an external program to use for playback of rendered animations. There are also some presets available.

### Text Editor

Here you can define an external text editor. Which allows you to edit text files externally. Which then can be done from the File menu in the text editor.

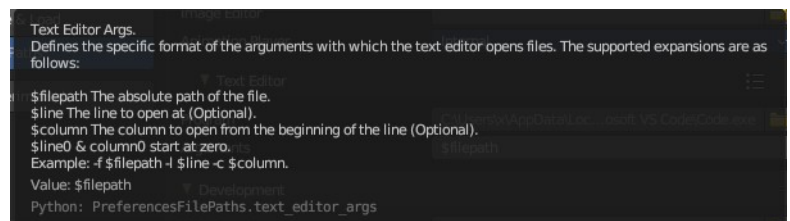

### Program

Enter the path to the external text editor.

### Arguments

Enter at least a filepath argument so that the code can be opened by the external editor. More arguments can be found in the tooltip.

## Development

### I18n Branches

The path to the /branches directory in your local repository translation copy. This allows translating the UI. See interface tab, the translation panel.

### Asset Libraries

The default paths for custom asset libraries. The functionality should be self explaining.

To change the path simply type in a path, or use the path picker at the end.

To add a new path to an asset library click at the + button below the list.

To remove a path click at the X button at the end.

### Asset List

The list of available asset libraries.

#### **Add**

Add a new asset library to the asset list.

#### **Remove**

Remove the selected library from the asset list.

#### **Path**

The path to the current selected asset library.

### Import Method

How to import the assets from the asset library into the scene.

#### **Append (Reuse Data)**

Imports the assets as a copied data. The data is fully imported, and not linked to the asset library. This method reuses existing materials or meshes.

#### **Append**

Imports the assets as a copied data. The data is fully imported, and not linked to the asset library. This method also imports every material and mesh from scratch, and can create duplicated redundant data.

#### **Link**

Links the assets to the assets in the asset library. The data is linked to the asset library. When you remove the

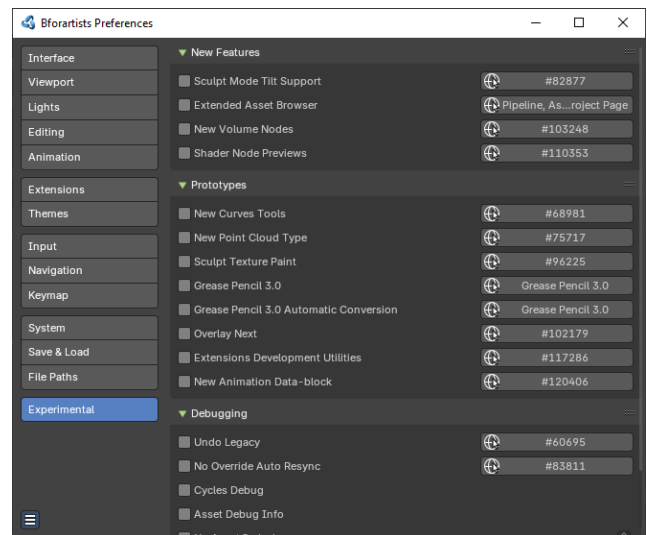

asset library then the linked data is also removed.

## Relative Path

Use relative paths when linking from this librar

# Experimental

Here you may find some experimental settings from the Blender development. We will not cover them here. They change very quick. Use at own risk!

## 31 Data System

### Table of content

Data System.....	1
Data-Blocks.....	1
Users (Garbage Collection).....	2
Fake User.....	2
Users (Sharing).....	2
Removing Data-Blocks.....	2
Data-Block Types.....	3

## Data System

Each `.blend` file contains a database. This database contains all scenes, objects, meshes, textures, etc. that are in the file.

A file can contain multiple scenes and each scene can contain multiple objects. Objects can contain multiple materials which can contain many textures. It is also possible to create links between different objects.

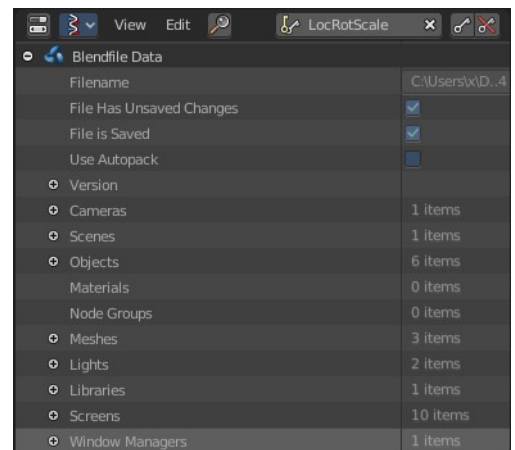

## Data-Blocks

The base unit for any Bforartists project is the data-block. Examples of data-blocks include: meshes, objects, materials, textures, node-trees, scenes, texts, brushes and even screens.

For clarity, bones, sequence strips and vertex groups are **not** data-blocks, they belong to armature, scene and mesh types respectively.

Some common characteristics:

- They're the primary contents of the `.blend` file.
- They can link to each other, for reuse and instancing. (*child/parent, object/object-data, with modifiers and constraints too*).
- Their names are unique.
- They can be added/removed/edited/duplicated.
- They can be linked between files (*only enabled for a limited set of data-blocks*)
- They can have their own animation data.
- They can have custom properties.

When doing more complex projects managing data-blocks becomes more important, especially when inter-linking `.blend` files.

## Users (Garbage Collection)

Bforartists follows the general rule where unused data is eventually removed.

Since its common to add and remove a lot of data while working, this has the advantage of not having to manually manage every single data-block.

This works by skipping zero user data-blocks when writing `.blend` files.

In some cases you want to save a data-block even when its unused (*typically for re-usable asset libraries*). see Fake User.

### Fake User

Since zero user data-blocks aren't saved. There are times when you want to force the data to be kept irrespective of its users.

If you're building a `.blend` file to serve as a library of things that you intend to link-to from *other* files, you'll need to make sure that they don't accidentally get deleted from the library file.

Do this by giving the data-blocks a *Fake User*, by pressing the *F* button next to the name of the data-block. This prevents the user count from ever becoming zero: therefore, the data-block won't be deleted. (since Bforartists doesn't keep track of how many other files link to this one.)

## Users (Sharing)

Many data-blocks can be shared among other data-blocks,

Examples where sharing data is common.

- Sharing textures among materials.
- Sharing meshes between objects (instances).
- Sharing animated actions between objects, for example to make all the lights dim together.

You can also share data-blocks between files, see.

- *linked libraries*.

## Removing Data-Blocks

As covered in Users (Garbage Collection), data-blocks are typically removed when they're no longer used.

There are some exceptions to this however.

The following data-blocks can be removed directly: Scene, Text, Group and Screen.

Other data-blocks such as groups and actions can be *Unlinked* from the *Outliner* context menu.

### Tip

Some data (images especially) is hard to keep track of, especially since image views are counted as users.

For data-blocks that can be unlinked - hold **Shift** while pressing on the *X* button, This force-clears the user-count, so the data-block will be removed on reload.

## Data-Block Types

For reference, here is a table of data-blocks types stored in `.blend` files.

**Link:** Library Linking, *supports being linked into other blend files.*

**Pack:** File Packing, *supports file contents being packed into the blend file.*

Type	Link	Pack	Description
Action	✓	✗	Stores animation F Curves. Used as data-block animation data, and the Non-Linear-Editor.
Armature	✓	✗	Skeleton used to deform meshes. Used as object-data & by the Armature Modifier.
Brush	✓	✗	Used by paint tools.
Camera	✓	✗	Used as object-data.
Curve	✓	✗	Used by camera, font & surface objects.
Font	✓	✓	References font files. Used by Font object-data.
GreasePencil	✓	✗	2D/3D sketch data. Used as overlay <i>helper</i> info, by the 3D-View, Image, Sequencer & Movie Clip editors.
Group	✓	✗	Reference object's. Used by dupli-groups & often library-linking.
Image	✓	✓	Image files. Used by textures & shader nodes.
Lamp	✓	✗	Used as object-data.
Lattice	✗	✗	Grid based lattice deformation. Used as object-data and by the Lattice Modifier.
Library	✗	✓	References to external <code>.blend</code> files. Access from the outliner's <i>Blend file</i> view.
LineStyle	✓	✗	Used by the FreeStyle render-engine.
Mask	✓	✗	2D animated mask curves. Used by compositing nodes & sequencer strip.
Material	✓	✗	Set shading and texturing render properties. Used by objects, meshes & curves.
Mesh	✓	✗	Geometry verts/edges/faces. Used as object-data.
MetaBall	✓	✗	An isosurface in 3D space. Used as object-data.
MovieClip	✓	✗	Reference to an image sequence or video file. Used in the motion-tracking editor.
NodeGroup	✓	✗	Collections of re-usable nodes. Used in the node-editor.
Object	✓	✗	An entity in the scene with location,

<b>Type</b>	<b>Link</b>	<b>Pack</b>	<b>Description</b>
			scale, rotation. Used by scenes & groups.
Particle	✓	✗	Particle settings. Used by particle systems.
Palette	✓	✗	Store color presets. Access from the paint tools.
Scene	✓	✗	Primary store of all data displayed and animated. Used as top-level storage for objects & animation.
Screen	✗	✗	Screen layout. Used by each window, which has its own screen.
ShapeKeys	✗	✗	Geometry shape storage, which can be animated. Used by mesh, curve and lattice objects.
Sounds	✓	✓	References to sound files. Used by speaker objects and the game-engine.
Speaker	✓	✗	Sound sources for a 3D scene. Used as object-data.
Text	✓	✗	Text data. Used by Python scripts and OSL shaders.
Texture	✓	✗	2D/3D textures. Used by materials, world and brushes.
World	✓	✗	Used by scenes for render environment settings.

## 32 Advanced - Command Line

### Table of content

Command Line Arguments.....	1
Render Options.....	1
Format Options.....	2
Animation Playback Options.....	2
Window Options.....	3
Python Options.....	3
Debug Options.....	3
Misc Options.....	4
Other Options.....	5
Experimental features.....	5
Argument Parsing.....	5
Argument Order.....	5
Environment Variables.....	6

## Command Line Arguments

You can start Bforartists from the command line to perform a specific task. To render in Background for example, without the graphical interface.

The general usage is: `Bforartists [arguments ...] [file] [arguments ...]`

Example - rendering an animation in background mode, allowing drivers and other scripts to run:

```
Bforartists --background --enable-autoexec my_movie.blend --render-anim
```

Or running a script with it:

```
Bforartists --myscene.blend --background --python myscript.py
```

In the background case the user-preferences are still used but you may want to override them.

- Enable with `-y` or `--enable-autoexec`
- Disable with `-Y` or `--disable-autoexec`

### Note

These command line arguments can be used to start a regular Bforartists instance and will still override the user-preferences.

## Render Options

- b, --background  
Run in background (often used for UI-less rendering)
- a, --render-anim  
Render frames from start to end (inclusive)

- S, --scene <name>  
Set the active scene <name> for rendering
- f, --render-frame <frame>  
Render frame <frame> and save it. +<frame> start frame relative, -<frame> end frame relative.
- s, --frame-start <frame>  
Set start to frame <frame>, supports +/- for relative frames too.
- e, --frame-end <frame>  
Set end to frame <frame>, supports +/- for relative frames too.
- j, --frame-jump <frames>  
Set number of frames to step forward after each rendered frame
- o, --render-output <path>

Set the render path and file name. Use // at the start of the path to render relative to the blend file.

The # characters are replaced by the frame number, and used to define zero padding.

- ani\_##\_test.png becomes ani\_01\_test.png
- test-#####.png becomes test-000001.png

When the filename does not contain #, The suffix ##### is added to the filename.

The frame number will be added at the end of the filename, eg:

```
Bforartists -b foobar.blend -o //render_ -F PNG -x 1 -a
```

//render\_ becomes //render\_####, writing frames as //render\_00001.png

- E, --engine <engine>  
Specify the render engine use -E help to list available engines
- t, --threads <threads>  
Use amount of <threads> for rendering and other operations [1-64], 0 for systems processor count.

## Format Options

- F, --render-format <format>  
Set the render format, Valid options are...  
TGA IRIS JPEG MOVIE IRIZ RAWTGA AVIRAW AVIJPEG PNG BMP FRAMESERVER  
(formats that can be compiled into Bforartists, not available on all systems)  
HDR TIFF EXR MULTILAYER MPEG AVICODEC QUICKTIME CINEON DPX DDS
- x, --use-extension <bool>  
Set option to add the file extension to the end of the file

## Animation Playback Options

- a <options> <file(s)>  
Playback <file(s)>, only operates this way when not running in background.
  - p <sx> <sy> Open with lower left corner at <sx>, <sy> -m Read from disk (Don't buffer) -f <fps> <fps-base> Specify FPS to start with -j <frame> Set frame step to <frame> -s <frame> Play from <frame> -e <frame> Play until <frame>

## Window Options

- w, --window-border  
Force opening with borders (default)
- W, --window-borderless  
Force opening without borders
- p, --window-geometry <sx> <sy> <w> <h>  
Open with lower left corner at <sx>, <sy> and width and height as <w>, <h>
- con, --start-console  
Start with the console window open (ignored if -b is set), (Windows only)
- no-native-pixels  
Do not use native pixel size, for high resolution displays (MacBook Retina)

## Python Options

- y, --enable-autoexec  
Enable automatic Python script execution
- Y, --disable-autoexec  
Disable automatic Python script execution (pydrivers & startup scripts), (default).
- P, --python <filename>  
Run the given Python script file
- python-text <name>  
Run the given Python script text block
- python-expr <expression>  
Run the given expression as a Python script
- python-console  
Run Bforartists with an interactive console
- python-exit-code  
Set the exit-code in [0..255] to exit if a Python exception is raised (only for scripts executed from the command line), zero disables.
- addons  
Comma separated list of addons (no spaces)

## Debug Options

- d, --debug  
  
Turn debugging on
  - Enables memory error detection
  - Disables mouse grab (to interact with a debugger in some cases)
  - Keeps Python's `sys.stdin` rather than setting it to `None`
- debug-value <value>  
Set debug value of <value> on startup
- debug-events  
Enable debug messages for the event system
- debug-ffmpeg  
Enable debug messages from FFmpeg library
- debug-handlers  
Enable debug messages for event handling

- debug-libmv**  
Enable debug messages from libmv library
- debug-cycles**  
Enable debug messages from Cycles
- debug-memory**  
Enable fully guarded memory allocation and debugging
- debug-jobs**  
Enable time profiling for background jobs.
- debug-python**  
Enable debug messages for Python
- debug-depsgraph**  
Enable debug messages from dependency graph
- debug-depsgraph-no-threads**  
Switch dependency graph to a single threaded evaluation
- debug-gpumem**  
Enable GPU memory stats in status bar
- debug-wm**  
Enable debug messages for the window manager, also prints every operator call
- debug-all**  
Enable all debug messages (excludes libmv)
- debug-fpe**  
Enable floating point exceptions
- disable-crash-handler**  
Disable the crash handler

## Misc Options

- factory-startup**  
Skip reading the startup.blend in the users home directory
- env-system-datafiles**  
Set the Bforartists\_SYSTEM\_DATAFILES environment variable
- env-system-scripts**  
Set the Bforartists\_SYSTEM\_SCRIPTS environment variable
- env-system-python**  
Set the Bforartists\_SYSTEM\_PYTHON environment variable
- nojoystick**  
Disable joystick support
- noglsl**  
Disable GLSL shading
- noaudio**  
Force sound system to None
- setaudio**  
Force sound system to a specific device NULL SDL OPENAL JACK
- h, --help**  
Print this help text and exit
- R**  
Register .blend extension, then exit (Windows only)
- r**  
Silently register .blend extension, then exit (Windows only)
- v, --version**

Print Bforartists version and exit

--

Ends option processing, following arguments passed unchanged. Access via Python's `sys.argv`

## Other Options

`/?`

Print this help text and exit (windows only)

`--debug-freestyle`

Enable debug/profiling messages from Freestyle rendering

`--debug-gpu`

Enable gpu debug context and information for OpenGL 4.3+.

`--disable-abort-handler`

Disable the abort handler

`--enable-new-depsgraph`

Use new dependency graph

`--verbose <verbose>`

Set logging verbosity level.

## Experimental features

`--enable-new-depsgraph`

Use new dependency graph

## Argument Parsing

Arguments must be separated by white space, eg:

```
Bforartists -ba test.blend
```

...will ignore the a

```
Bforartists -b test.blend -f8
```

...will ignore 8 because there is no space between the -f and the frame value

## Argument Order

Arguments are executed in the order they are given. eg:

```
Bforartists --background test.blend --render-frame 1 --render-output '/tmp'
```

...will not render to /tmp because `--render-frame 1` renders before the output path is set

```
Bforartists --background --render-output /tmp test.blend --render-frame 1
```

...will not render to /tmp because loading the blend file overwrites the render output that was set

```
Bforartists --background test.blend --render-output /tmp --render-frame 1
```

...works as expected.

## Environment Variables

### **Bforartists\_USER\_CONFIG:**

Directory for user configuration files.

### **Bforartists\_USER\_SCRIPTS:**

Directory for user scripts.

### **Bforartists\_SYSTEM\_SCRIPTS:**

Directory for system wide scripts.

### **Bforartists\_USER\_DATAFILES:**

Directory for user data files (icons, translations, ..).

### **Bforartists\_SYSTEM\_DATAFILES:**

Directory for system wide data files.

### **Bforartists\_SYSTEM\_PYTHON:**

Directory for system python libraries.

### **TEMP:**

Store temporary files here.

### **TMP:**

or \$TMPDIR Store temporary files here.

### **SDL\_AUDIODRIVER:**

LibSDL audio driver - alsa, esd, dma.

### **PYTHONHOME:**

Path to the python directory, eg. /usr/lib/python.

## Scripting & Extending Bforartists

### Python

Python is an interpreted, interactive, object-oriented programming language.

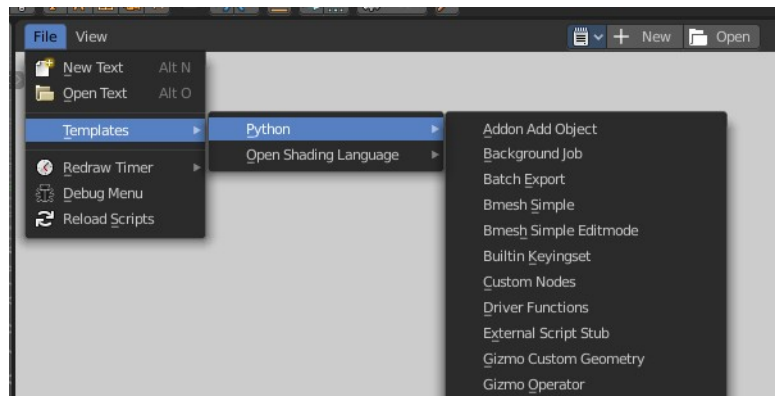

Python scripts are a way to extend Bforartists functionality. Most areas of Bforartists can be scripted, including Animation, Rendering, Import and Export, Object Creation and the scripting of repetitive tasks.

This can be done by the Blender Python API (Application Programming Interface). It comes also with an introduction to scripting and some examples. <https://docs.blender.org/api/blender2.8/index.html>

### Extending Bforartists

You can either write scripts, and perform them in the text editor. Scripts must be loaded and executed from scratch every time you need them. Or you can write complete addons. Addons can be activated, and loads with Bforartists.

You can find quite a few example scripts in the text editor in the file menu.

## Scripting & Security

The ability to include Python scripts within blend files is valuable for advanced tasks such as rigging, automation and using the game-engine, however it poses a security risk since Python doesn't restrict what a script can do.

Therefore, you should only run scripts from sources you know and trust.

Automatic execution is disabled by default, however some blend files need this to function properly.

When a blend file tries to execute a script and is not allowed, a message will appear in the header with the option to **Reload Trusted** or **Ignore** the message.

## Scripts in Blend Files

### Auto Execution

Here are the different ways blend files may automatically run scripts.

#### Registered Text-Blocks

A text block can have its *Register* option enabled which means it will load on start.

#### Animation Drivers

Python expressions can be used to *Drive* values and are often used in more advanced rigs and animations.

#### Game Engine Auto-Start

Scripts are often used for game logic, blend files can have *Auto Start* enabled with runs the game on load.

### Manual Execution

There are other ways scripts in a blend file may execute that require user interaction (therefor will run even when auto-execution is off), but you should be aware that this is the case since it's not necessarily obvious.

- Running a script in the text editor (*ok, this is obvious!*).
- Rendering with FreeStyle - *FreeStyle uses scripts to control line styles*
- Running the Game-Engine.

## Controlling Script Execution

Blender files can also contain scripts. Which can be auto run when you load the blend file. Auto running scripts can be a security issue. There are two ways to control script execution in blend files. In the load dialog for a blend file. Or in the Preferences.

In the Blender file selector you will see down left the checkbox **Trusted source**.

Enable it to allow auto execution of the scripts in the blend file.

**Auto-Run Python Scripts in the Preferences in the Save & Load Panel** allows you to run scripts in blend files automatically.

The Excluded Paths edit box below allows you to exclude certain directories. You can for example exclude the download directory. And allow auto run from all other directories at your computer.

## BAM Asset Manager

Refactoring linked `.blend` files is a common practice in a production environment. While some basic operations can be accomplished within Blender, sometimes it is more practical to perform them on the command line or via a script. During the production of *Cosmos Laundromat* (Gooseberry Open Movie Project) the *BAM Asset Manager* (BAM) was developed. The original scope of BAM included client-server asset management tools going beyond Blender, but it was later refocused on core utilities to perform two operations:

- blendfile packing
- automatic dependencies remapping

### Installing BAM

BAM is a standalone Python package, that can be run on any system without any particular configuration. The only requirement is Python 3 (and pip, the Python package manager, to easily install BAM).

Windows, Linux and macOS provide different ways to install Python 3 and pip. Check out the online docs to learn more about a specific platform.

Once Python 3 and pip are available, BAM can be installed via command line by typing:

```
pip3 install blender-bam
```

After a successful installation, the `bam` command will be available. By typing it and pressing the Enter key, all the available sub commands will be displayed.

### `bam pack`

This command is used for packing a `.blend` file and *all* its dependencies into a `.zip` file for redistribution.

```
usage: bam pack [-h] [-o FILE] [-m MODE] [-e PATTERNS] [-a] [-q] [-c LEVEL]
           paths [paths ...]
```

You can simply pack a blend file like this to create a zip-file of the same name.

```
bam pack /path/to/scene.blend
```

You may also want to give an explicit output directory. The example shows how to pack a blend with maximum compression for online downloads

```
bam pack /path/to/scene.blend --output my_scene.zip --compress=best
```

The command provides several options to adapt to different workflows (final distribution, partial extraction, rendering).

**-o, --output <FILE>**

Output file or a directory when multiple inputs are passed

**-m, --mode <MODE>**

Output file or a directory when multiple inputs are passed. Possible choices: ZIP, FILE

**-e, --exclude <PATTERN(S)>**

Optionally exclude files from the pack.

```
--exclude="*.png"
```

Using Unix shell-style wildcards (*case insensitive*).

```
--exclude="*.txt;*.avi;*.wav"
```

Multiple patterns can be passed using the ; separator.

**-a, --all-deps**

Follow all dependencies (unused indirect dependencies too)

**-q, --quiet**

Suppress status output

**-c, --compress <LEVEL>**

Compression level for resulting archive Possible choices: default, fast, best, store

**--repo <DIR PATH>**

Specify a “root” path from where to pack the selected file. This allows for the creation of a sparse copy of the production tree, without any remapping.

**--warn-external**

Report external libraries errors (missing paths)

## Examples

Consider the following directory layout, and in particular the file *01\_01\_A.lighting.blend* with its linked libraries.

```
~/agent327/
├─ lib/
│  ├─ chars/
│  │  ├─ agent.blend ----->|
│  │  ├─ boris.blend ----->|
│  │  └─ barber.blend ----->|
│  └─ scenes/
│     ├─ 01-opening ----->|
│     ├─ 01_01_A.lighting.blend <--| < BAM pack this file
│     └─ 01_01_A.anim.blend ----->|
```

Once we run `bam pack /scenes/01-opening/01_01_A.lighting.blend` we obtain a `01_01_A.lighting.zip` inside of which we find the following structure.

```
~/01_01_A.lighting
├── 01_01_A.lighting.blend
├── /
│   ├── 01_01_A.anim.blend
│   └── lib/
│       ├── chars/
│       └── agent.blend
│           └── boris.blend
```

Note how all paths have been remapped relative to the placement of `01_01_A.lighting.blend` in the root of the output. If we run `bam pack /scenes/01-opening/01_01_A.lighting.blend --repo ~/agent327`, the output will be different.

```
~/01_01_A.lighting
├── lib/
│   ├── chars/
│   │   ├── agent.blend
│   │   └── boris.blend
├── scenes
│   └── 01-opening/
│       ├── 01_01_A.lighting.blend < The BAM packed file
│       └── 01_01_A.anim.blend
```

In this case no path is remapped, and we simply strip out any file that is not referenced as a direct or indirect dependency of `01_01_A.lighting.blend`. This is effectively a sparse copy of the original production tree.

## bam remap

Remap blend file paths

usage: `bam remap [-h] {start,finish,reset} ...`

This command is a 3 step process:

- first run `bam remap start .` which stores the current state of your project (recursively).
- then re-arrange the files on the file system (rename, relocate).
- finally run `bam remap finish` to apply the changes, updating the `.blend` files internal paths.

```
cd /my/project
```

```
bam remap start .
mv photos textures
mv barbershop_v14_library.blend barberhop_libraray.blend
bam remap finish
```

### Note

Remapping creates a file called `bam_remap.data` in the current directory. You can relocate the entire project to a new location but on executing `finish`, this file must be accessible from the current directory.

### Note

This command depends on files unique contents, take care not to modify the files once remap is started.

## ***Subcommands***

### **remap start**

Start remapping the blend files

usage: bam remap start [-h] [-j] [paths [paths ...]]

-j, --json

Generate JSON output

### **remap finish**

Finish remapping the blend files

usage: bam remap finish [-h] [-r] [-d] [-j] [paths [paths ...]]

-r, --force-relative

Make all remapped paths relative (even if they were originally absolute)

-d, --dry-run

Just print output as if the paths are being run

-j, --json

Generate JSON output

### **remap reset**

Cancel path remapping

usage: bam remap reset [-h] [-j]

## 34 Advanced - Working Limits

### Table of content

Working Limits.....	1
Space.....	1
Time.....	1
Text Fields.....	2

## Working Limits

There are some limits that you should take into account. Precision issues when working with mesh data for example.

### Space

While object positions, vertex locations are not clamped, larger values become increasingly imprecise.

To get an idea of the precision you can work with using different scales.

Here's a table of scales and their associated accuracy.

<b>10:</b>	1/1,048,576 <sup>th</sup>
<b>100:</b>	1/131,072 <sup>th</sup>
<b>1,000:</b>	1/16,384 <sup>th</sup>
<b>10,000:</b>	1/1,024 <sup>th</sup>
<b>100,000:</b>	1/128 <sup>th</sup>
<b>1,000,000:</b>	1/16 <sup>th</sup>

#### Hint

For a rough rule of thumb, values within -5,000/+5,000 are typically reliable (range of 10,000).

Internally *single precision* floating point calculations are used.

### Time

The maximum number of frames for each scene is currently 500,000, and allows for continuous shots for duration's of:

**24 fps:** 5 hours, 47 seconds.

**25 fps:** 5 hours, 33 seconds.

**30 fps:** 4 hours, 37 seconds.

**60 fps:** 2 hours, 18 seconds.

### Note

In practice, a finished work is typically composed of output from many scenes. So this limit does not prevent you from creating longer works.

## Text Fields

Fixed strings are used internally, and while it is not useful to list all limits, here are some common limits. *Text fields are used for various things like data-block names, modifiers, vertex-groups, UV-layers...*

<b>directory:</b>	767 characters
<b>file-name:</b>	255 characters
<b>file-path:</b>	1023 characters
<b>identifier:</b>	63 characters

### Note

Multi-byte encoding means some Unicode characters use more than a single ASCII character.

## Brush Panels

This addon is optional and deactivated by default.

This adds a **Brushes Tab** to most painting and drawing modes and objects. This includes an individual panel per brush operator listing all brush types dynamically, including all user created brushes. This also includes the ability to display custom icons and is responsive per the toolshelf standards.

**Note**

To activate/deactivate an addon, go to Edit – Preferences – Addons tab – and untick any activated addons.

If you’d like to keep your addons for future use, you can either **save the preferences**, or activate them on demand per workspace in the workspace settings in the property shelf.

## Use

To use, go into a paint mode (**Sculpt, Texture Paint, Vertex Paint, Weight Paint or Grease Pencil Draw Mode**), select the Brush tab in the Tool Shelf to the left, and then select a brush. When you select a brush, the button will automatically select the brush operator and select the brush type stored in the brush library. You can link/append and create any new brush type for later use – you can also assign iconography on demand.

If you don’t see the toolshelf tabs, go to View and turn on Tool Shelf Tabs.

To add brushes, you can use the add button in the Property Shelf under the Tool tab or in the Header brush type dropdown, you can add new brushes or remove brushes.

**Note**

Keep in mind a removed brush is still stored in orphan data till you purge data or save and reload the file. If brush type contains a (fake) user, this brush will

not be purged from the file.

To add icons to brushes, in the Brushes panel in the Tool tab of the Property Shelf, you can use the Custom Icon to load any image as a brush icon.

You can find the Brush tab and panels in the **3D View Editor** or the **Image Editor** with the correct painting modes.

*For more information, please refer to the relevant chapters on the painting modes per object type.*

## Brush Panels and Modes

### Mesh Objects

These brush panels are included with all mesh object painting modes.

#### Sculpt Mode

The Sculpt mode activated from the top left of the 3D View or by hotkey.

##### **Draw**

All Draw brush types.

##### **Draw Sharp**

All Draw Sharp brush types.

##### **Clay**

All Clay brush types.

##### **Clay Strips**

All Clay Strips brush types.

##### **Layer**

All Layer brush types.

##### **Inflate**

All Inflate brush types.

##### **Blob**

All Blob brush types.

##### **Crease**

All Crease brush types.

## ***Smoothing***

All Smoothing brush types.

## ***Flatten***

All Flatten brush types.

## ***Fill***

All Fill brush types.

## ***Scrape***

All Scrape brush types.

## ***Multipane Scrape***

All Multipane Scrape brush types.

## ***Pinch***

All Pinch brush types.

## ***Grab***

All Grab brush types.

## ***Elastic Deformation***

All Elastic Deformation brush types.

## ***Snake Hook***

All Snake Hook brush types.

## ***Thumb***

All Thumb brush types.

## ***Pose***

All Pose brush types.

## ***Nudge***

All Nudge brush types.

## ***Rotate***

All Rotate brush types.

## ***Topology***

All Topology brush types.

## ***Boundary***

All Boundary brush types.

## ***Cloth***

All Cloth brush types.

## ***Simplify***

All Simplify brush types.

## ***Mask***

All Mask brush types.

## ***Draw Face Sets***

All Draw Face Sets brush types.

## ***Displacement Erase***

All Displacement Erasebrush types.

## ***Displacement Smear***

All Displacement Smear brush types.

## ***Paint***

All Paint brush types.

## **Vertex Paint**

The Vertex Paint mode activated from the top left of the 3D View or by hotkey.

### ***Draw***

All Draw brush types.

### ***Smear***

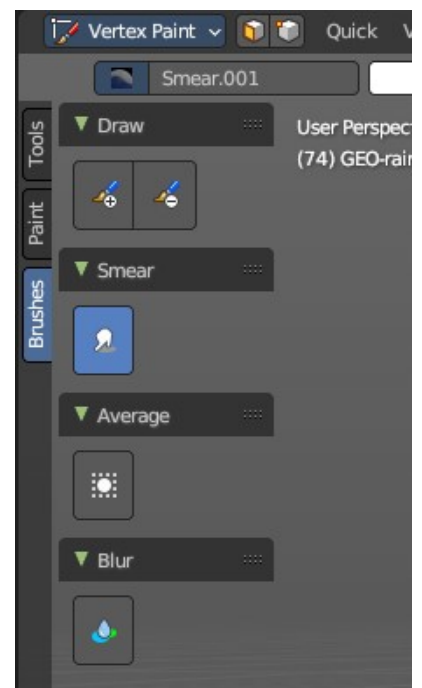

All Smear brush types.

### ***Average***

All Average brush types.

### ***Blur***

All Blur brush types.

## Weight Paint

The Weight Paint mode activated from the top left of the 3D View or by hotkey.

### **Draw**

All Draw brush types.

### **Smear**

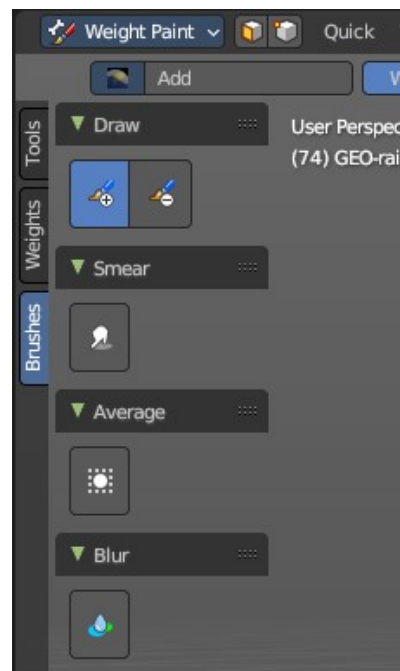

All Smear brush types.

### **Average**

All Average brush types.

### **Blur**

All Blur brush types.

## Texture Paint

The Texture Paint mode activated from the top left of the 3D View or by hotkey.

### **Draw**

All Draw brush types.

### **Soften**

All Soften brush types.

### **Smear**

All Smear brush types.

### **Clone**

All Clone brush types.

### **Fill**

All Fill brush types.

### **Mask**

All Mask brush types.

## Grease Pencil

These brush panels are included with the Grease Pencil object Draw Mode.

## **Draw Mode**

The draw mode activated from the top left of the 3D View or by hotkey.

### ***Draw***

All Draw brush types.

### ***Erase***

All Erase brush types.

### ***Fill***

All Fill brush types.

### ***Tint***

All Tint brush types.

## 35.2 Core Extension - Presentation Slider

### Table of content

Bforartists Presentation Slider.....	1
Operators.....	1
Slides.....	1
Previous.....	2
Next.....	2
Loop Animation.....	2
Hide Interface.....	2
Use.....	2
Scenes as “Slides”.....	2
Animated Transitions.....	3

## Presentation Slider

This addon is optional and deactivated by default.

This adds a **Presentations Slides** panel to the View tab in the sidebar of 3D View Editor. This then allows to use buttons to go to next scene or previous scene as if they were presentation slides.

**Note**

To activate/deactivate an addon, go to Edit – Preferences – Addons tab – and untick any activated addons.

If you’d like to keep your addons for future use, you can either **save the preferences**, or activate them on demand per workspace in the workspace settings in the property shelf.

## Operators

This addon adds a hook (app handler) when using the slides buttons which then allows the animation timeline to stop when it reaches the end frame - to get default looping timeline animation, press the Loop Animation button in the Addon panel.

**Note**

Works best when playback is on **Play Every Frame** in the Option panel of the Timeline Editor.

### Slides

This group of buttons controls the slides operations.

**Note**

These buttons switch to the Scene defined by alphabetical order of the Scene names.

**Previous**

Switch to the previous scene, then playback the animation timeline then stop on the last frame. When at the first scene, it will then go to the last scene.

**Next**

Switch to the next scene, then playback the animation timeline then stop on the last frame. When at the last scene, it will then go to the first scene.

**Loop Animation**

Removes the hook to playback the timeline animation once, and resets to playback to loop the animation timeline per default. This will also playback the animation.

**Hide Interface**

This adds an additional operator to hide all toolshelves if the header is showing. This will also maximize the 3D View and hide all overlays. Ideal for having a fullscreen without overriding the operating system desktop and allowing a quick switch to show/hide the interface for tutorial presentations.

**Use**

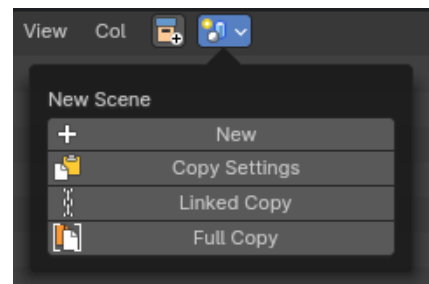

**Scenes as “Slides”**

To use the addon, organize your presentation content in Scene containers in the Outliner Editor – and create new slides using Linked Copy of a Scene or New Scenes. Every “presentation slide” is a Scene container.

Name the Scenes in alphabetical or numerical order for the sequence of “slides” you would like to present.

For best user experience, switch the Outliner Editor to Scene mode to manage your “slides”.

## Animated Transitions

For animated transitions: animate the camera and scene content within the timeline start and end frames. When the first Scene is ready, Link Copy or create a New Scene from the first Scene, then change the second Scene's timeline to start from the previous Scene's end frame, camera position, and/or linked collections.

### Example:

Scene 01 – set timeline from 0-30 frames: animate camera from position A to B

Scene 02 – set timeline from 30-60 frames: animate camera from position B to C

Scene 03 – set timeline from 60-90 frames: animate camera from position C to D

## 35.3 Core Extension - 3D Sequencer

    - Sequencer Sync – Scene Strip Overlay Property..... 6
- Use..... 7
  1. Create Scenes..... 7
  2. Set the Master Scene..... 7
  3. Set the Master Scene to the sequencer Timeline..... 7
  4. Add Scene Strips to the sequencer Timeline..... 7
  4. Synchronize Timeline to 3D View..... 8

## 3D Sequencer

This addon is optional and deactivated by default.

This adds the ability to use the sequencer with the 3D View with a timeline. Using Scene Strips, you can switch the 3D View scenes with a master sequencer scene, like in a video

editor.

This addon is thanks to Spa Studios, Znight, and Draise.

### Note

To activate/deactivate an addon, go to Edit – Preferences – Addons tab – and untick any activated addons. If you'd like to keep your addons for future use, you can either **save the preferences**, or activate them on demand per workspace in the workspace settings in the property shelf.

## Header Tools

### Sync Header Button

Toggles Synchronization Timeline to 3D View.

To use, set the sequencer timeline to the master scene then toggle to synchronize the 3D with the Sequencer.

## Header

### Sequencer – Scene

An additional header menu for Scene Strip operators in the Sequencer Editor.

### Adjust Timing

Adjusts the timing of the active Scene Strip by extending or compressing the Scene Strip length directly from the Sequencer timeline.

## Toggle Active Scene Strip

Updates the current scene to the active scene strip.

If the timeline in sequencer header is not set, this toggles the current scene to active Scene Strip in the sequencer.

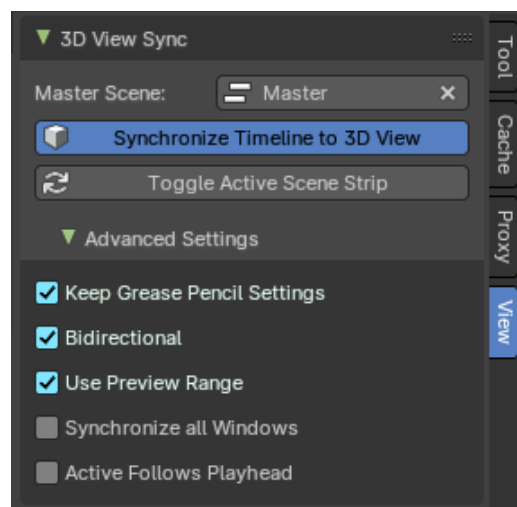

## Play Master Scene

Toggle playback of the master scene from the sequencer timeline.

# Panels and Operators

## Sequencer – 3D View Sync panel

This panel located in the Sequencer sidebar View tab has the group of operators, properties and buttons define how the Sequencer synchronizes the Timeline to 3D View.

## Master Scene Selector

The master scene selector is where you define which the scene should contain all the children Scene Strips in the Sequencer timeline. The selected scene with the containing children Scene Strips in the Sequencer will be your Master Scene.

Each Scene Strip in the timeline will change the active 3D View camera and active scene when the Synchronize Timeline to 3D View operator is on.

**Note:** *The Master Scene should also be selected in the sequencer header to be “pinned” before syncing the 3D View, as the synchronization only work on the selected Sequencer timeline.*

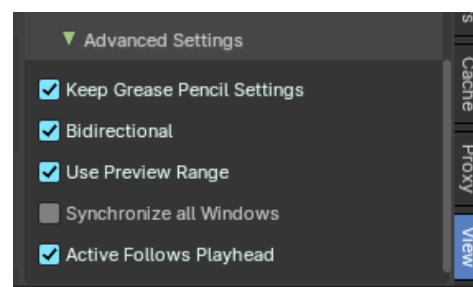

## Advanced Settings Sub-Panel

These define the advanced settings for Sequencer synchronizes the Timeline to the 3D View.

### Keep Grease Pencil Settings

Keep active Grease Pencil tool settings while switching and navigating

Scene Strips from the timeline.

### ***Bidirectional***

Whether changing the Active Scene's time should update the Master Scene's current frame.

### ***Use Preview Range***

Update the preview range of current strip's scenes to match the useful range of the strip.

### ***Synchronize all Windows***

Whether the 3D View Sync impacts all the Main Windows.

### ***Active Follows Playhead***

Update the active strip while scrubbing the sequencer.

## **3D View - Sequencer Sync Panel**

This panel displays information from the Sequencer in the 3D View, including the active Scene Strip with assigned scene and camera. This panel is located in the View tab of the 3D View sidebar.

### **Master Scene Selector**

The master scene selector is where you define which the scene should contain all the children Scene Strips in the Sequencer timeline to influence the 3D View. The selected scene with the containing children Scene Strips in the Sequencer will be your Master Scene.

Each Scene Strip in the timeline will change the active 3D View camera and active scene when the Synchronize Timeline to 3D View operator is on in the Sequencer View tab.

### **Sequencer Scene Strips List**

This shows the list of scene strips from the Master Scene timeline from the Sequencer. On the left is the Scene Strip name, center is the active camera, and to right is the assigned scene to the Scene Strip.

### **Scene Strip Settings**

This box shows the active Scene Strip in the 3D View with

properties to select the assigned scene, the active camera selector and other operators.

### ***Scene Selector***

Select the active scene for the active Scene Strip.

### ***Create Child Scene Setup***

Duplicate Linked the active scene as a new scene then update the active Scene Strip to the new scene.

### ***Active Camera Selector***

Overrides the scene active camera and camera markers to a fixed camera.

### ***Set Active Camera***

If None is set, the Scene Strip camera behavior defaults to no active camera or last active Scene camera.

### ***Set Active Scene Camera***

Sets the camera for the Scene Strip to the Active Camera. If Active is set, the Scene Strip camera behavior defaults to the bound cameras to timeline marker or to the active Scene camera.

### ***Set Active Camera to None***

If the Scene Strip has an active camera override, you can set it to None to revert the Scene Strip camera behavior defaults to no active camera or last active Scene camera.

### ***Select the Active Camera***

Selects the Active Camera in the scene.

## Overlays

## Dopesheet - Options

### Sequencer Sync – Scene Strip Overlay Property

Toggles the retiming widget of the active Scene Strip in the Dopesheet. Changing the preview start and end of the strip will also change the Scene Strip length in the Sequencer.

The green handle retimes the start of the Scene Strip.

The red handle retimes the end of the Scene Strip.

# Use

## 1. Create Scenes

To set a timeline in the sequencer, first create a master scene and concurrent scenes for your shots. Each scene can have their individual cameras, collections, animation and render settings. You can also link collections and data between scenes.

## 2. Set the Master Scene

The Master Scene is where the Scene Strip cameras and animation strips are defined. This timeline information will synchronize with the 3D view and vice versa.

In the view tab of the 3D View in the Sequencer Sync panel, you can set the Master Scene in the panel, or set the Master Scene in the view tab of the Sequencer in the 3D View Sync panel. This master scene will define how the Scene Strips control the 3D View.

## 3. Set the Master Scene to the sequencer Timeline

After you have defined the Master Scene, you must define the Timeline to the Master Scene. Once you have this set, you can now playback and synchronize the 3D View to the sequencer Timeline.

**Note:** You can also “pin” the any scene to the sequencer timeline.

## 4. Add Scene Strips to the sequencer Timeline.

You can add Scene Strip to the sequencer Timeline from from the add menu.

Now you can use the Dopesheet overlay to retime your scenes, and the Sequencer to change the sequence, cut, and re-order your scenes.

You can also retime your Scene Strips in the sequencer.

## 4. Synchronize Timeline to 3D View

This button in the header will start the realtime sequencer timeline synchronization to the 3D View.

**Note:** *If you are in the master scene in the 3D View, toggle or switch to one of the Scene Strip scenes and then it will update from the sequencer timeline.*

## 35.4 Core Extension - Power User Tools

## Power User Tools

UI: BFA - Power User Tools

**Description:** Additional set of user experience tools and operators to assist with every day use for the power user.

**Location:** Varios consistent locations for the power user - customize as you need!

**File:** C:\3D\_Stuff\bfa\_build\_windows\_Release\_x64\_vc17\_Release\bin\4.2\scripts\addons\bfa\_toolshelf\_addon\_template\\_init\_.py

**Author:** Andres Stephens (Draise)

**Version:** 0.2.1

**Warning:** This is a Bforartists exclusive addon for the time being

**Internet:** [Report a Bug](#)

**Preferences:**

Animation:

- Insert/Remove Frames Operators
- Animation Toolshelf Operators

This addon is optional and deactivated by default.

This is an addon with an additional set of user experience tools and operators to assist every day use.

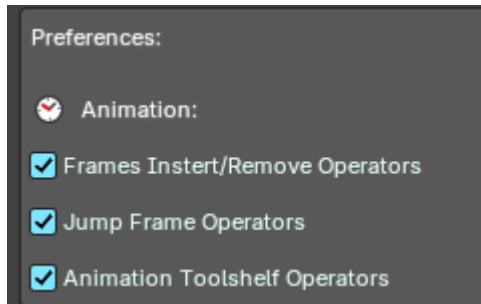

This addon is thanks to Andres Stephens (Draise).

### Note

To activate/deactivate an addon, go to Edit – Preferences – Addons tab – and untick any activated addons. If you'd like to keep your addons for future use, you can either **save the preferences**, or activate them on demand per workspace in the workspace settings in the property shelf.

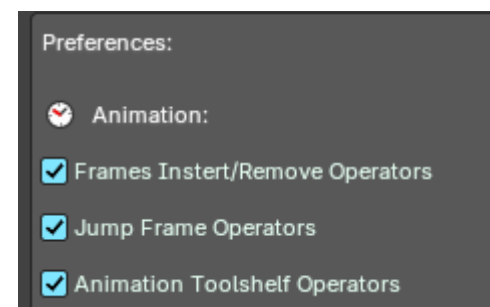

## Preferences

In the addon preferences, you can toggle which group of operators or user experience customization to help assist your needs.

## Animation

These are operators to assist and improve the animation user experience.

### Frames Insert/Remove Operators Toggle

Toggle to add operators to insert/remove a frame to the left or right of the timeline cursor. Useful for grease pencil and stop motion animation.

#### Operators

- Insert Frame Left
- Remove Frame Left

- Insert Frame Right
- Remove Frame Right

## Location of operators

3D View Editor – Object Header Menu – Animation Sub-Menu

3D View Editor – Toolshelf – Animation Tab – Animation Panel

Timeline Editor – Header Buttons on the right

Dopesheet Editor – Key Header Menu

Graph Editor – Key Header Menu

3D View Header – Grease Pencil – Edit mode - Grease Pencil Header menu – Animation sub-menu.

3D View Header – Grease Pencil – Draw mode - Draw Header menu – Animation sub-menu.

3D View Header – Grease Pencil – Edit mode - Animation Panel

3D View Header – Grease Pencil – Draw mode - Animation Panel

3D View Header – Grease Pencil – Sculpt mode - Animation Panel

3D View Header – Grease Pencil – Vertex mode - Animation Panel

## Frames Jump Operators Toggle

Toggle to add the Frame Jump operators from the header of the Timeline Editor.

## Location of operators

Timeline Editor – Header Buttons on the right

## Animation Toolshelf Operators Toggle

Toggle to add the animation operators from the header to the toolshelf.

Useful for general animation keyframe use from the 3D View.

## Operators

For more information of these operators, please visit the chapter **Editors - 3D Viewport - Header - Object menu**

You can alternatively view these operators in the 3D View Header – Object/Pose Header menu – Animation sub-menu.

## Location of operators

3D View Editor – Toolshelf – Animation Tab – Animation Panel

3D View Header – Object/Pose Header menu – Animation sub-menu.

3D View Header – Object/Pose Header menu – Animation sub-menu.

# Operators

## Animation Operators

### Insert Frame Left

Inserts an empty frame and nudges all frames to the left of the time cursor. Useful for grease pencil and stop motion animation.

### Remove Frame Left

Removes a frame on the right of the timeline cursor and nudges all frames towards the timeline cursor.

**Note:** *Current frame on timeline cursor will be removed.*

### Insert Frame Right

Inserts an empty frame and nudges all frames to the right of the time cursor Useful for grease pencil and stop motion animation.

### Remove Frame Right

Removes a frame on the right of the timeline cursor and nudges all frames towards the timeline cursor.

**Note:** *Current frame on timeline cursor will be removed.*

### Jump Frame Left

Move the timeline cursor to the left and jump by the number of frames defined in the center property.

### Jump Frame Right

Move the timeline cursor to the right and jump by the number of frames defined in the center property.

# Use

## 1. Activate the addon

In the user preferences Addons tab, search for “Power User” and activate the addon.

## 2. Customize which operators you would need in the preferences

Here you will find categories and groups of operators. Mouse over which group of operators to see the tooltip to learn more.

## 35 Bforartists Extensions

## Bforartists Extensions

Bforartists comes with default and included extensions based addons and themes to help improve the user experience. Some of these can be activated by the user and saved in the preferences for daily use. Many addons are shipped which include specific user experience improvements. Feel free to activate and use when necessary.

## Default Extensions Addons

These addons are turned on by default and shipped with Bforartists. Most come directly from the Blender repository. These addons are split into official and community addons.

### Activated Addons:

#### Official

- Animation: Pose Library
- Import-Export: BioVision Motion Capture (BVH) format
- Import-Export: FBX format
- Import-Export: STL format
- Import-Export: Scalable Vector Graphics (SVG) 1.1 format
- Import-Export: Stanford PLY format
- Import-Export: UV Layout
- Import-Export: Wavvefront OBJ format (legacy)

- Import-Export: glTF 2.0 format
- Cycles

## Official – Bforartists Exclusive

- Bforartists: Create IsoCam
- Bforartists: Default Asset Library
- Import-Export: Web3d X3D/VRML2 format
- Mesh: Mesh Tools – Bforartists version
- Bforartists: Smart Delete
- Bforartists: Align View Buttons
- Bforartists: Important Hotkeys Overlays
- Bforartists: User Settings
- Bforartists: 3D View Reset

### Note

To activate/deactivate an addon, go to Edit – Preferences – Addons tab – and untick any activated addons. If you'd like to keep your addons for future use, you can either **save the preferences**, or activate them on demand per workspace in the workspace settings in the property shelf.

## Included Addons

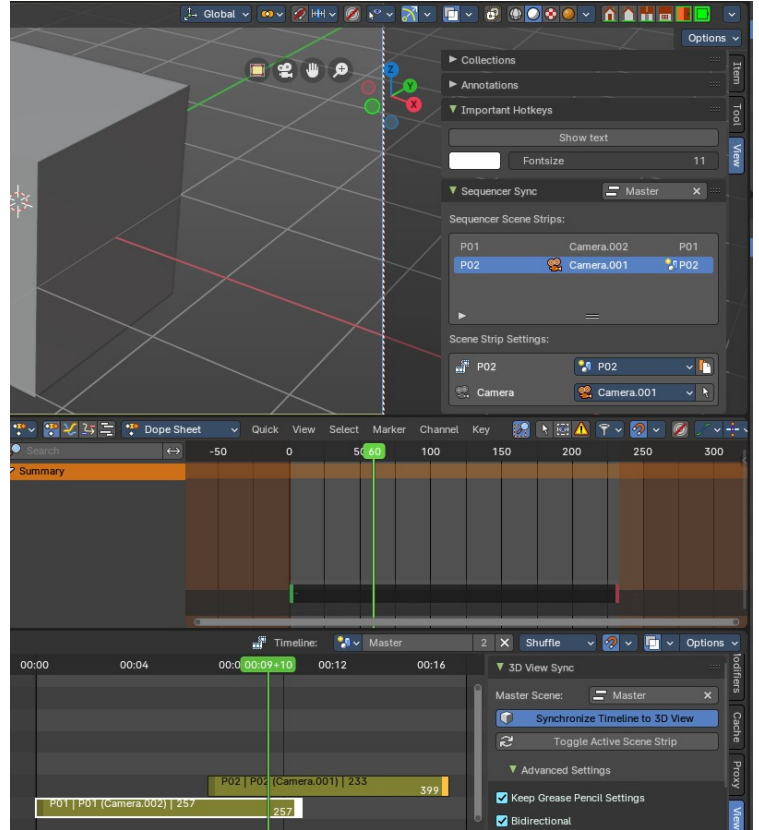

Bforartists has included custom addons to improve the user experience. Most are activated by default, some are optional.

- 3D Sequencer
- Align View Buttons
- Brush Panels
- Create IsoCam
- Default Asset Library
- Find and Replace
- Important Hotkeys Overlays
- Mesh: Mesh Tools – Bforartists version
- Power User Tools
- Presentation Slider
- Reset 3D View
- Smart Delete
- User Settings
- X Ray Weight Paint

## 3D Sequencer

This addon is optional and deactivated by default. This adds the ability to use the sequencer with the 3D View with a timeline. Using Scene Strips, you can switch the 3D View scenes with a master sequencer scene, like in a video editor.

This addon is thanks to Spa Studios, Znight, and Draise.

## Align View Buttons

This addon is activated by default. This includes quick overlay and view settings that you can personalize to the top right of the 3D View Editor.

## Brush Panels

This addon is optional and deactivated by default. This adds a Brush Tab to most painting and drawing modes and objects. This includes panels per brush operator listing all brush types dynamically, including all listed brushes. This also includes custom icons and is responsive per the toolshelf standards.

This addon is thanks to Iyad Ahmed and Draise.

## Create Isocam

This addon is activated by default. Add the option to create orthographic iso cameras from the 3D View Add menu.

## Default Asset Library

This addon is activated by default. This includes a default asset library shipped with Bforartists. To know more about what this library includes and how to access it, refer to chapter *Asset Browser – Default Asset library*

## Find and Replace

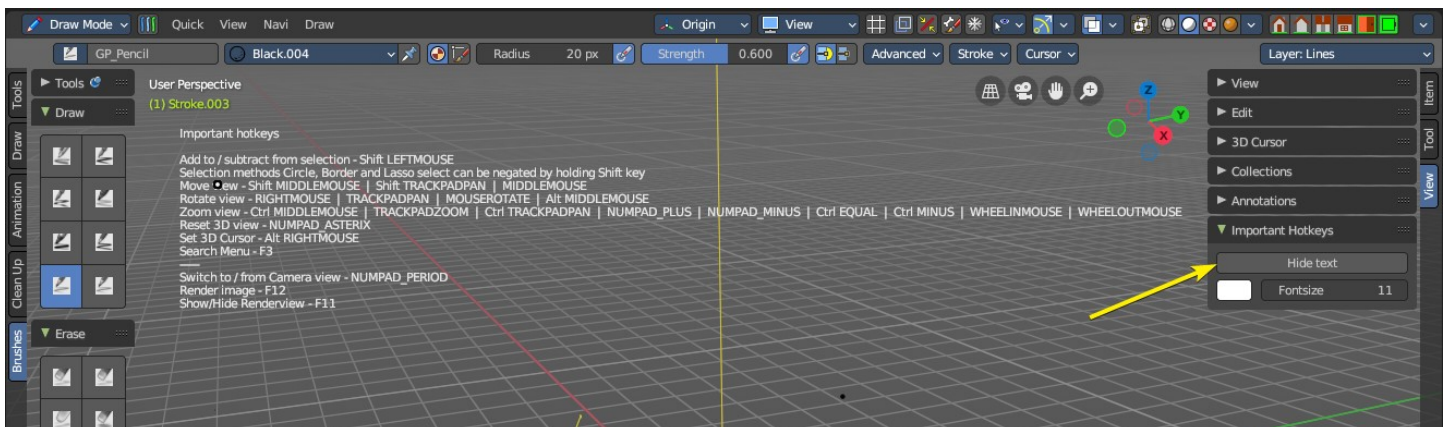

This addon is activated by default. This addon allows to press SHIFT+RMB to start searching from a pop-up panel in the Text Editor, and also adds the popup panel to the header.

## Important Hotkeys

This addon is activated by default. This addon includes a button to show important hotkeys as an overlay in the 3D View, showing hotkeys.

This addon is thanks to Reiner.

## Mesh: Mesh Tools – Bforartists version

This addon is activated by default. This addon is a default Blender addon that has been modified to work with Bforartists in a better integrated way.

## Power User Tools

This addon is optional and deactivated by default. This is an additional set of user experience tools and operators to assist every day use for the power user.

## Presentation Slider

This addon is optional and deactivated by default. Adds controls to switch to the next Scene then plays the animation once, useful for presentation slides setup as Scenes. For more information in how to use it, refer to chapter *Bforartists Presentation Slider*

This addon is thanks to Draise.

## Reset 3D View

This addon is activated by default. This adds an operator to the interface to reset the view – both accessible in the 3D View – View header menu entry and the optional header buttons to the top right. You can alternatively use the \* key on the Numpad.

## Smart Delete

This addon is activated by default. This addon improves the user experience of deleting geometry, so that you can save a few clicks every time you want to remove geometry. Now it detects what you have selected and removes it in a predictable way. To use it, press DEL on selected geometry.

This addon is thanks to Reiner.

## User Settings

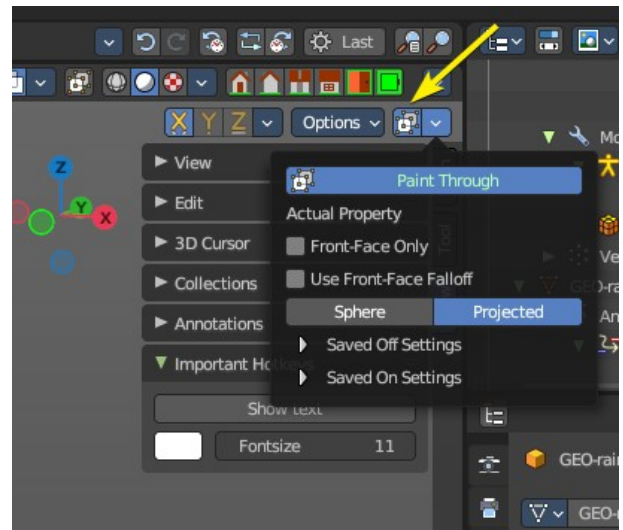

This addon is activated by default. This stores the toolbar settings. It is **important** that you **do not turn this addon off**, it will break Bforartists functionality.

## X Ray Weight Paint

This addon is optional and deactivated by default. This addon helps automate the process of setting up xray painting for armature weight painting. This helps set up various user settings for a desired user experience.

This addon is thanks to Blender Boi. You can find the repository here:

<https://github.com/BlenderBoi/XRayWeightPaint->

## Troubleshooting

There are some common problems in Bforartists. Before you proceed make sure your computer meets the minimum requirements. And make sure your drivers are up to date and your graphics card is supported.

## Troubleshooting the 3D View

### Objects Invisible in Camera View

If you have a large scene, viewing it through Camera View may not display all of the Objects in the scene. One possibility may be that the clipping distance of the camera is too low. The camera will only show objects that fall within the clipping range.

### Performance

#### Slow Selection

Bforartists uses OpenGL drawing for selection, some graphics card drivers are slow at performing this operation.

This becomes especially problematic on dense geometry.

Possible Solutions:

### OpenGL Occlusion Queries (User Preference)

See User Preferences ▶ System ▶ Selection

This option defaults *Automatic*, try setting this to *OpenGL Occlusion Queries*, since there is a significant performance difference under some configurations.

### Upgrade OpenGL Driver

In some cases slow selection is resolved by using updated drivers. *It's generally good to use recent drivers when using 3D software.*

### Select Centers (Workaround)

In *Object Mode*, holding `Ctrl` while selecting uses the object center point. While this can be useful on its own, it has the side-effect of not relying on OpenGL selection.

### Change Draw Modes (Workaround)

Using *Wireframe* or even *Bounding Box* draw modes can be used to more quickly select different objects.

#### Note

Obviously the workarounds listed here aren't long term solutions, but it's handy to know if you're stuck using a system with poor OpenGL support.

Ultimately, if none of these options work out it may be worth upgrading your hardware.

## Navigation

### Lost in Space

When navigating your scene, you may accidentally navigate away from your scene and find yourself with a blank view-port.

The solution is to use the Reset 3D View operator in the View menu. This resets the 3D view to the initial state.

### Invisible Limit Zooming In

This problem lies in the nature of the default zooming method. It zooms towards a point in the scene. And when it reaches this point, then it cannot zoom any further.

One solution is to zoom out and move towards the object instead of zooming.

You can also try some other zoom methods. Dolly or Border Zoom doesn't have these problems.

## Tools

### Invalid Selection

There are times when selection fails under some configurations, often this is noticeable in mesh *Edit Mode*, selecting vertices/edges/faces where random elements are selected.

Internally Bforartists uses OpenGL for selection, so the graphics card driver is relied on giving correct results.

Possible Solutions:

### **Disable Anti-Aliasing (FSAA, Multi-Sampling)**

This is by far the most common cause of selection issues.

There are known problems with some graphics cards when using FSAA/multi-sampling.

You can disable this option by:

- Turning FSAA/multi-sampling off in your graphics card driver options.
- Turning *Multi-Sampling* off in the system preferences.

### **Change Anti-Aliasing Sample Settings**

Depending on your OpenGL configuration, some specific sample settings may work, while others fail.

Unfortunately finding working configuration involves trial & error testing.

### **Upgrade OpenGL Driver**

As with any OpenGL related issues, using recent drivers can resolve problems.

However it should be noted that this is a fairly common problem and remains unresolved with many drivers.

## **Troubleshooting Graphics Hardware**

Bforartists makes use of OpenGL, which is typically hardware accelerated.

This means issues with the graphics card hardware and drivers can impact on Bforartists's behavior. This page lists some known issues using Bforartists on different graphics hardware and how to trouble-shoot them.

### **Performance**

When the entire interface very slow and unresponsive (*even with the default startup scene*). This is likely a problem with the OpenGL configuration.

Unfortunately in this situation you may have to do some of your own tests to find the cause, here are some common causes and possible solutions.

#### **Upgrade your OpenGL Driver**

If you're experiencing any strange graphics problems with Bforartists, its always good to double check you're using the latest drivers.

#### **Disable Anti-Aliasing (FSAA, Multi-Sampling)**

See Invalid Selection, Disable Anti-Aliasing.

#### **Change the Window Draw Method**

This is set in the system preferences. Its selected automatically, however when experiencing problems its worth checking if changing this resolves interface drawing problems.

## Troubleshooting Crashes

Like every other software, Bforartists can crash. The most common causes of Bforartists crashes are.

- Running out of memory.
- Issues with graphics hardware/drivers.
- Bugs in Bforartists.

Firstly, you may be able to recover your work with File ▶ Recover Last Session.

To prevent the problem from happening again, you can check that the graphics drivers are up to date, upgrade your machine's hardware (the RAM or graphics card), and disable some options that are more memory intensive:

- Disable *Region Overlap* and *Triple buffering* at User Preferences ▶ System ▶ Window Draw Method.
- Using multi sample, anti-aliasing also increase the memory usage and make display slower.
- On Linux, the Window Manager (KDE, Gnome, Unity) may be using hardware accelerated effects (eg. window shadows and transparency) that are using up the memory that Bforartists needs. Try disabling the desktop effects or switch to a light-weight Window Manager.

## Recovering from mistakes or problems

Bforartists provides a number of ways for the user to recover from mistakes, and reduce the chance of losing their work in the event of operation errors, computer failures, or power outages. There are two ways for you to recover from mistakes or problems:

### At the User Level (Relating to *Actions*)

- For your actions, there are options like *Undo*, *Redo* and an *Undo History*, used to roll back from mistakes under normal operation, or return back to a specific action.
- Bforartists also has new features like *Repeat* and *Repeat History*, and the new *Redo Last* which you can use in conjunction with the options listed.

### At the System Level (Relating to *Files*)

- There are options to save your files like *Auto Save* that saves your file automatically over time, and *Save on Quit*, which saves your Bforartists file automatically when you exit Bforartists.

#### Note

In addition to these functions being enabled by default, the *Save on Quit* functionality cannot be disabled.

As a general rule for every software usage: save often, save very often, and don't forget to save often!

## Options for Files (System Level)

### Save and Auto Save

Computer crashes, power outages or simply forgetting to save can result in the loss or corruption of your work. To reduce the chance of losing files when those events occur, Bforartists can use an *Autosave* function. The *Save and Load* tab of the *User Preferences* window allows you to configure the two ways that Bforartists provides for you to regress to a previous version of your work.

### Save on Quit

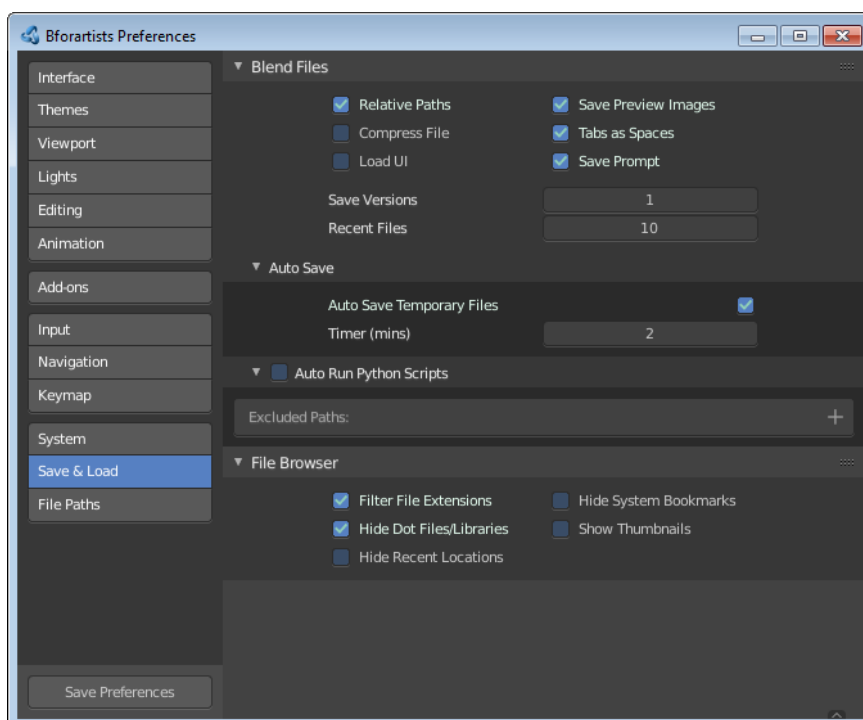

The function *Save on Quit* is enabled by default in Bforartists. Bforartists will always save your files when you quit the application under normal operation.

### Save Versions

This option tells Bforartists to keep the indicated number of saved versions of your file in your current working directory when you manually save a file. These files will have the extension: `.blend1`, `.blend2`, etc., with the number increasing to the number of versions you specify. Older files will be named with a higher number. e.g. With the default setting of `2`, you will have three versions of your file: `*.blend` (your last save), `*.blend1` (your second last save) and `*.blend2` (your third last save).

### Auto Save Temporary Files

Checking this box tells Bforartists to *automatically* save a backup copy of your work-in-progress to the Temp directory (refer to the *File* panel in the *User Preferences* window for its location). This will also enable the *Timer (mins)* control which specifies the number of minutes between each Auto Save. The default value of the Bforartists installation is `5` (5 minutes). The minimum is `1`, and the Maximum is `60` (Save at every one hour). The Auto Saved files are named using a random number and have a `.blend` extension.

### Tip

#### Compress Files

The option to Compress files will try to compact your files whenever Bforartists is saving them. Large Scenes, dense Meshes, big Textures or lots of elements in your Scene will result in a big `.blend` being created. This option could slow down Bforartists when you quit, or under normal operation when Bforartists is saving your backup files. In fact, using this option you will trade processor time for file space.

## Recovering Auto Saves

### Recover Last Session

File ▶ Recover Last Session will open the `quit.blend` that is saved into the *Temp* directory when you exit Bforartists. Note that files in your *Temp* directory are deleted when you reboot.

### Recover Auto Save

File ▶ Recover Auto Save... allows you to open the Auto Saved file. After loading the Auto Saved version, you may save it over the current file in your working directory as a normal `.blend` file.

Recover Autosave will open the file browser.

### Important

When recovering an Auto Saved file, you will lose any changes made since the last *Auto Save* was performed. Only **one** Auto Saved file exists for each project (i.e. Bforartists does not keep older versions - hence you won't be able to go back more than a few minutes with this tool).

## Compatibility (OSX)

### Mouse Motion Jitters (SmoothMouse)

#### Problem

When grabbing an object or orbiting the view, cursor motion is jittery.

#### Solutions

- Uninstall **SmoothMouse**.
- Disable Continuous Grab

## Compatibility (Windows)

### Bforartists Hangs on Window Duplication (Nahimic for MSI)

#### Problem

Accessing Window ▶ Duplicate Window, hangs Bforartists, using 100% of one core.

#### Solution

Uninstall **Nahimic for MSI**

## 37 Glossary

This page lists definitions for terms used in Bforartists and this manual.

### **Action Safe**

Area of the screen visible on most devices. Place content inside it to ensure it does not get cut off.

### **Active**

When many items are selected, the last selected item will be the active one. Used in situations where the interface only shows options for one item at a time.

### **Aliasing**

Rendering artifacts in the form of jagged lines.

### **Alpha Channel**

Additional channel in an image for transparency.

#### **Straight Alpha**

Method where RGBA channels are stored as (R, G, B, A) channels, with the RGB channels unaffected by the alpha channel. This is the alpha type used by paint programs such as Photoshop or Gimp, and used in common file formats like PNG, BMP or Targa. So, image textures or output for the web are usually straight alpha.

#### **Premultiplied Alpha**

Method where RGBA channels are stored as  $(R \times A, G \times A, B \times A, A)$ , with the alpha multiplied into the RGB channel.

This is the natural output of render engines, with the RGB channels representing the amount of light that comes toward the viewer, and alpha representing how much of the light from the background is blocked. The OpenEXR file format uses this alpha type. So, intermediate files for rendering and compositing are often stored as premultiplied alpha.

#### **Conversion (Straight/Premultiplied) Alpha**

Conversion between the two alpha types is not a simple operation and can involve data loss, as both alpha types can represent data that the other cannot, though it is often subtle.

Straight alpha can be considered to be an RGB color image with a separate alpha mask. In areas where this mask is fully transparent, there can still be colors in the RGB channels. On conversion to premultiplied alpha, this mask is applied and the colors in such areas become black and are lost.

Premultiplied alpha, on the other hand, can represent renders that are both emitting light and letting through light from the background. For example, a transparent fire render might be emitting light, but also letting through all light from objects behind it. On converting to straight alpha, this effect is lost.

### **Ambient Light**

The light that comes from the surrounding environment as a whole.

### **Ambient Occlusion**

A ratio of how much ambient light a surface point would be likely to receive. If a surface point is under a foot or table, it will end up much darker than the top of someone's head or the tabletop.

### **Animation**

Simulation of motion.

### **Anti-aliasing**

Is the technique of minimizing aliasing, by e.g. rendering multiple samples per pixel.

### **Armature**

An Object consisting of bones. Used to rig characters, props, etc.

### **Axis**

A reference line which defines coordinates along one cardinal direction in n-dimensional space.

### **Axis Angle**

Rotation method where X, Y, and Z correspond to the axis definition, while W corresponds to the angle around that axis, in radians.

### **Baking**

The process of computing and storing the result of a potentially time-consuming calculation so as to avoid needing to calculate it again.

### **Bevel**

The operation to chamfer or bevel edges of an object.

### **Bezier**

A computer graphics technique for generating and representing curves.

### **Blend Modes**

#### **Color Blend Modes**

Methods for blending two colors together.

### **Bone**

The building block of an Armature. Made up of a Head, Tail and Roll Angle which define a set of local axes and a point of rotation at the Head.

### **Boolean**

A type of logic dealing with binary true/false states.

### **Bounding Box**

The box that encloses the shape of an object. The box is aligned with the local space of the object.

### **Bump Mapping**

Technique for simulating slight variations in surface height using a greyscale “heightmap” texture.

### **BVH**

Bounding Volume Hierarchy. File format. A hierarchical structure of geometric objects.

### **Caustics**

The optical phenomenon of light concentration focused by specular reflections or refracting objects. In example observable on light passing through a glass of water onto a table or the pattern at the bottom of a swimming pool.

In rendering this refers to diffuse reflected light paths after a glossy or refraction bounce.

### **Child**

An Object that is affected by its Parent.

### **Chroma / Chrominance**

In general, a resulting image color decomposition, where its (L or Y) luminance channel is separated. There are two different contexts whereas this term is used:

#### **Video systems**

Refers to the general color decomposition resulting in Y (Luminance) and C (Chrominance) channels, whereas the chrominance is represented by:  $U = (\text{Blue} - \text{Luminance})$  and  $V = (\text{Red} - \text{Luminance})$ .

#### **Matte compositing**

Refers to a point in the color gamut surrounded by a mixture of a determined spectrum of its RGB neighboring colors. This point is called Chroma key and this key (a chosen color) is used to create an Alpha Mask. The total amount of gamut space for this chrominance point is defined by users in a circular or square-shaped format.

### **Chromaticities**

The coordinates of the primaries on the CIE 1931 xy chromaticity diagram.

### **Clamp / Clamping**

Limits a variable to a range. The values over or under the range are set to the constant values of the range's minimum or maximum.

### **Collection**

A device for organizing objects. See also Collections.

### **Color Gamut**

A gamut traditionally refers to the volume of color a particular color model/space can cover. In many instances, it is often illustrated via a 2D model using CIE Yxy coordinates.

### **Color Space**

A coordinate system in which a vector represent a color value. By doing so, the color space defines three things:

The exact color of each of the primaries. The White Point. A transfer function

### **sRGB**

A color space that uses the Rec .709 primaries and white point but, with a slightly different transfer function.

### **HSV**

Three values often considered as more intuitive (human perception) than the RGB system.

### **Hue**

The Hue of the color.

### **Saturation**

Also known as colorfulness, saturation is the quantity of hue in the color (from desaturated – a shade of gray – to saturated – brighter colors).

### **Value**

The brightness of the color (dark to light).

### **HSL**

Hue, Saturation

### **Luminance**

The intensity of light either in an image/model channel, or emitted from a surface per square unit in a given direction.

### **YUV**

Luminance-Chrominance standard used in broadcasting analog PAL (European) video.

### **YCbCr**

Luminance-ChannelBlue-ChannelRed Component video for digital broadcast use, whose standards have been updated for HDTV and commonly referred to as the HDMI format for component video.

### **Concave Face**

Face in which one vertex is inside a triangle formed by other vertices of the face.

### **Constraint**

A way of controlling one object with data from another.

### **Convex Face**

Face where, if lines were drawn from each vertex to every other vertex, all lines would remain in the face. Opposite of a concave face.

### **Co planar**

Refers to any set of elements that are all aligned to the same 2D plane in 3D space.

### **Crease**

Property of an edge. Used to define the sharpness of edges in subdivision surface meshes.

### **Curve**

A type of object defined in terms of a line interpolated between Control Vertices. Available types of curves include Bezier, NURBS and Poly.

### **Cyclic**

Often referring to an object being circular. This term is often associated with Curve.

### **Data User**

An existing Blender object, which is using its own data, or linked data (data owned and controlled by another Blender object).

### **Diffuse Light**

Even, directed light coming off a surface. For most things, diffuse light is the main lighting we see. Diffuse light comes from a specific direction or location and creates shading. Surfaces facing towards the light source will be brighter, while surfaces facing away from the light source will be darker.

### **Directional Light**

The light that has a specific direction, but no location. It seems to come from an infinitely far away source, like the sun. Surfaces facing the light are illuminated more than surfaces facing away, but their location does not matter. A Directional Light illuminates all objects in the scene, no matter where they are.

### **Displacement Mapping**

A method for distorting vertices based on an image or texture. Similar to Bump Mapping, but instead operates on the mesh's actual geometry. This relies on the mesh having enough geometry to represent details in the image.

### **Display Referenced**

Refers to an image whose Luminance channel is limited to a certain range of values (usually 0-1). The reason it is called display referenced is because a display cannot display an infinite range of values. So, the term Scene Referenced must go through a transfer function to be converted from one to the other.

### **DOF**

Depth Of Field. The distance in front of and behind the subject which appears to be in focus. For any given lens setting, there is only one distance at which a subject is precisely in focus, but focus falls off gradually on either side of that distance, so there is a region in which the blurring is tolerable. This region is greater behind the point of focus than it is in front, as the angle of the light rays change more rapidly; they approach being parallel with increasing distance.

### **Double Buffer**

Technique for rendering and displaying content on the screen. Blender uses two buffers (images) to render the

interface, the content of one buffer is displayed while rendering occurs on the other buffer. When rendering is complete, the buffers are switched.

### **Edge**

Straight segment (line) that connects two vertices, and can be part of a face.

### **Edge Loop**

Chain of edges belonging to consecutive quads. An edge loop ends at a pole or a boundary. Otherwise, it is cyclic.

### **Edge Ring**

Path of all edges along a face loop that share two faces belonging to that loop.

### **Empty**

An Object without any Vertices, Edges or Faces.

### **Euler / Euler Rotation**

Rotation method where rotations applied on each X, Y, Z axis component.

### **F-Curve**

A curve that holds the animation values of a specific property.

### **Face**

Mesh element that defines a piece of surface. It consists of three or more edges.

### **Face Loop**

Chain of consecutive quads. A face loop stops at a triangle or N-gon (which do not belong to the loop), or at a boundary. Otherwise, it is cyclic.

### **Face Normal**

The normalized vector perpendicular to the plane that a face lies in. Each face has its own normal.

### **Fake User**

A special Data User, a program construct that is used to mark an object (e.g. material) to be saved in a blend-file, even when no Real User is using the object. Objects that are not used by any Data User are not included in saved blend-files.

### **Field of View**

The area in which objects are visible to the camera. Also see Focal Length.

### **Focal Length**

The distance required by a lens to focus collimated light. Defines the magnification power of a lens. Also see Field of View.

### **Frame Types**

In video compression, a frame can be compressed by several different algorithms. These algorithms are known

as picture types or frame types and there are three major types: I, P, and B frames.

### **I-frames**

The least compressible but don't require other video frames to decode.

### **P-frames**

Use data from previous frames to decompress and are more compressible than I-frames.

### **B-frames**

Use both previous and forward frames for data reference to get the highest amount of compression.

### **Gamma**

An operation used to adjust the brightness of an image.

### **Geometric Center**

The mean average of the positions of all vertices making up the object.

### **Gimbal**

A pivoted support that allows the rotation of an object about a single axis.

### **Gimbal Lock**

The limitation where axes of rotation can become aligned, losing the ability to rotate on an axis (typically associated with euler rotation).

### **Global Illumination**

A super-set of radiosity and ray tracing. The goal is to compute all possible light interactions in a given scene, and thus, obtain a truly photo realistic image. All combinations of diffuse and specular reflections and transmissions must be accounted for. Effects such as color bleeding and caustics must be included in a global illumination simulation.

### **Global Space**

The global world coordinates. Is equal to World Space.

### **Glossy Map**

A black and white texture that defines where the object is glossy.

### **HDRI**

High Dynamic Range Image. A set of techniques that allow a far greater dynamic range of exposures than normal digital imaging techniques. The intention is to accurately represent the wide range of intensity levels found in real scenes, ranging from direct sunlight to the deepest shadows.

### **Head**

A sub component of a Bone. The point of rotation for the bone has X, Y, and Z coordinates measured in the Local Space of the Armature Object. Used in conjunction with the Tail to define the local Y axis of the bone in Pose Mode. The larger of the two ends when displayed as an Octahedron.

## **Interpolation**

The process of calculating new data between points of known value, like keyframes.

## **Inverse Kinematics**

The process of determining the movement of interconnected segments of a body or model. Using ordinary Kinematics on a hierarchically structured object you can, for example, move the shoulder of a puppet. The upper and lower arm and hand will automatically follow that movement. IK will allow you to move the hand and let the lower and upper arm go along with the movement. Without IK the hand would come off the model and would move independently in space.

## **IOR**

Index Of Refraction. A property of transparent materials. When a light ray travels through the same volume it follows a straight path. However, if it passes from one transparent volume to another, it bends. The angle by which the ray is bent can be determined by the IOR of the materials of both volumes.

## **Keyframe**

A frame in an animated sequence drawn or otherwise constructed directly by the user. In classical animation, when all frames were drawn by animators, the senior artist would draw these frames, leaving the “in between” frames to an apprentice. Now, the animator creates only the first and last frames of a simple sequence (keyframes); the computer fills in the gap.

## **Keyframing**

Inserting Keyframes to build an animated sequence.

## **Lattice**

A type of object consisting of a non-render-able three-dimensional grid of vertices.

## **Light Bounces**

Refers to the reflection or transmission of a light ray upon interaction with a material. See also Light Paths.

## **Local Space**

A 3D coordinate system that originates (for Objects) at the Object Origin. or (for Bones) at the Head of the Bone.

## **Luminance**

The intensity of light either in an image/model channel, or emitted from a surface per square unit in a given direction.

## **Manifold**

Manifold meshes, also called water-tight meshes, define a closed non-self-intersecting volume (see also non-manifold). A manifold mesh is a mesh in which the structure of the connected faces in a closed volume will always point the normals (and there surfaces) to the outside or to the inside of the mesh without any overlaps. If you recalculate those normals, they will always point at a predictable direction (To the outside or to the inside of the volume). When working with non-closed volumes, a manifold mesh is a mesh in which the normals will always define two different and non-consecutive surfaces. A manifold mesh will always define an even number

of non-overlapped surfaces.

### **MatCap**

Stands for “material capture”, using an image to represent a complete material including lighting and reflections.

### **Matte**

Matte painting is the technique to union real life footage like a photo with cg content like a mesh.

### **Mask**

A greyscale image used to include or exclude parts of an image. A matte is applied as an Alpha Channel, or it is used as a mix factor when applying Color Blend Modes.

### **Mesh**

Type of object consisting of vertices, edges and faces.

### **Micro polygons**

A polygon roughly the size of a pixel or smaller.

### **MIP / Mip-map / Mip-mapping**

‘MIP’ is an acronym of the Latin phrase ‘multum in parvo’, meaning ‘much in little’. Mip-maps are progressively lower resolution representations of an image, generally reduced by half squared interpolations using anti-aliasing. Mip-mapping is the process used to calculate lower resolutions of the same image, reducing memory usage to help speed visualization, but increasing memory usage for calculations and allocation. Mip-mapping is also a process used to create small anti-aliased samples of an image used for texturing. The mip-mapping calculations are made by CPU's, but modern graphic processors can be selected for this task and are way faster.

### **MIS**

Multiple Importance Sampling. A process of estimating the direction of light rays to improve sampling quality.

### **Motion Blur**

The phenomenon that occurs when we perceive a rapidly moving object. The object appears to be blurred because of our persistence of vision. Simulating motion blur makes computer animation appear more realistic.

### **Multi sampling**

Rendering multiple samples per pixel, for anti-aliasing.

### **N-gon**

A face that contains more than four vertices.

### **NDOF**

A general term used to describe a 3D mouse, or any input devices which supports more degrees of freedom than a conventional 2D input device, see: NDOF (3D Mouse).

### **Non-linear Animation**

Animation technique that allows the animator to edit motions as a whole, not just the individual keys. Non-linear animation allows you to combine, mix, and blend different motions to create entirely new animations.

### **Non-manifold**

Non-Manifold meshes essentially define geometry which cannot exist in the real world. This kind of geometry is not suitable for several types of operations, especially those where knowing the volume (inside/outside) of the object is important (refraction, fluids, booleans, or 3D printing, to name a few). A non-manifold mesh is a mesh in which the structure of a non-overlapped surface (based on its connected faces) will not determine the inside or the outside of a volume based on its normals, defining a single surface for both sides, but ended with flipped normals. When working with non-closed volumes, a non-manifold mesh will always determine at least one discontinuity in the normal directions, either by an inversion of a connected loop, or by an odd number of surfaces. A non-manifold mesh will always define an odd number of surfaces.

There are several types of non-manifold geometry:

Some borders and holes (edges with only a single connected face), as faces have no thickness.

Edges and vertices not belonging to any face (wire).

Edges connected to three or more faces (interior faces).

Vertices belonging to faces that are not adjoining (e.g. two cones sharing the vertex at the apex).

### **Normal**

The normalized vector perpendicular to a surface.

Normals can be assigned to vertices, faces and modulated across a surface using normal mapping.

### **Normal Mapping**

Is similar to Bump mapping, but instead of the image being a greyscale heightmap, the colors define in which direction the normal should be shifted, the three color channels being mapped to the three directions X, Y and Z. This allows more detail and control over the effect.

### **NURBS**

Non-uniform Rational Basis Spline

A computer graphics technique for generating and representing curves and surfaces.

### **Object**

Container for a type (Mesh, Curve, Surface, Metaball, Text, Armature, Lattice, Empty, Camera, Light) and basic 3D transform data (Object Origin).

### **Object Center / Object Origin**

A reference point used to position, rotate, and scale an Object and to define its Local Space coordinates.

### **Octahedron**

An eight-sided figure commonly used to depict the Bones of an Armature.

### **OpenGL**

The graphics system used by Blender (and many other graphics applications) for rendering 3D graphics, often taking advantage of hardware acceleration.

### **Overscan**

The term used to describe the situation. when not all of a televised image is present on a viewing screen.

### **Parent**

An Object that affects its Child objects.

### **Parenting**

Creating a Parent-Child relationship between two objects.

### **Particle system**

Technique that simulates certain kinds of fuzzy phenomena, which are otherwise very hard to reproduce with conventional rendering techniques. Common examples include fire, explosions, smoke, sparks, falling leaves, clouds, fog, snow, dust, meteor tails, stars, and galaxies, or abstract visual effects like glowing trails, magic spells. Also used for things like fur, grass or hair.

### **Phong**

Local illumination model that can produce a certain degree of realism in three-dimensional objects by combining three elements: diffuse, specular and ambient for each considered point on a surface. It has several assumptions – all lights are points, only surface geometry is considered, only local modeling of diffuse and specular, specular color is the same as light color, ambient is a global constant.

### **Pivot Point**

The pivot point is the point in space around which all rotations, scalings and mirror transformations are centered.

### **Pixel**

The smallest unit of information in a 2D raster image, representing a single color made up of red, green, and blue channels. If the image has an alpha channel, the pixel will contain a corresponding fourth channel.

### **Pole**

Vertex where three, five, or more edges meet. A vertex connected to one, two, or four edges is not a pole.

### **Polygon**

A geometry face with multiple vertices. A tri has three vertices, a quad has four vertices, an N-gon has more than four vertices. And they all are polygons.

### **Pose Mode**

Used for posing, keyframing, weight painting, constraining and parenting the bones of an armature.

### **Posing**

Moving, Rotating and Scaling the bones of an armature to achieve an aesthetically pleasing pose for a character.

### **Premultiplied Alpha**

If an alpha channel is used in an image, there are two common representations that are available: straight (unassociated) alpha, and premultiplied (associated) alpha. With straight alpha, the RGB components represent the color of the object or pixel, disregarding its opacity. With premultiplied alpha, the RGB components represent the emission of the object or pixel, and the alpha represents the occlusion.

### **Primaries**

In color theory, primaries (often known as primary colors) are the abstract lights, using an absolute model, that make up a color space.

### **Primitive**

A basic object that can be used as a basis for modeling more complicated objects.

### **Procedural Texture**

Computer generated (generic) textures that can be configured via different parameters.

### **Projection**

In computer graphics, there are two common camera projections used. Perspective and Orthographic.

#### **Perspective**

A perspective view is geometrically constructed by taking a scene in 3D and placing an observer at point O. The 2D perspective scene is built by placing a plane (e.g. a sheet of paper) where the 2D scene is to be rendered in front of point O, perpendicular to the viewing direction. For each point P in the 3D scene a PO line is drawn, passing by O and P. The intersection point S between this PO line and the plane is the perspective projection of that point. By projecting all points P of the scene you get a perspective view.

#### **Orthographic**

In an orthographic projection, you have a viewing direction but not a viewing point O. The line is then drawn through point P so that it is parallel to the viewing direction. The intersection S between the line and the plane is the orthographic projection of the point P. By projecting all points P of the scene you get the orthographic view.

### **Proxy**

For video editing, a proxy is a smaller version of the original file, typically using an optimized video codec and lower resolution version (faster to load) that stands in for the main image or video.

When proxies are built, editing functions like scrubbing and scrolling and compositing is much faster but gives lower resolution and slightly imprecise result.

### **Quad / Quadrilateral / Quadrangle**

Face that contains exactly four vertices.

### **Quaternion / Quaternion Rotation**

Rotation method where rotations are defined by four values (X, Y, Z, and W). X, Y, and Z also define an axis, and W an angle, but it is quite different from Axis Angle.

### **Radiosity**

A global lighting method that calculates patterns of light and shadow for rendering graphics images from three-dimensional models. One of the many different tools which can simulate diffuse lighting in Blender.

### **Seed**

The seed is a value that gets used for random number generators. It is not really random since the same seed will always produce the same random number set. But random enough for most randomization needs. Choosing another seed value will produce another set of random numbers.

### **Ray Tracing**

Rendering technique that works by tracing the path taken by a ray of light through the scene, and calculating reflection, refraction, or absorption of the ray whenever it intersects an object in the world. More accurate than scanline, but much slower.

### **Real User**

A Blender object, which is a Data User. Opposite of Fake User, which is only a program construct.

### **Refraction**

The change in direction of a wave due to a change in velocity. It happens when waves travel from a medium with a given index of refraction to a medium with another. At the boundary between the media, the wave changes direction; its wavelength increases or decreases but frequency remains constant.

### **Render**

The process of computationally generating a 2D image from 3D geometry.

### **RGB**

A color model based on the traditional primary colors, Red/Green/Blue. RGB colors are also directly broadcasted to most computer monitors.

### **Rig**

A system of relationships that determine how something moves. The act of building of such a system.

### **Roll / Roll Angle**

The orientation of the local X and Z axes of a Bone. Has no effect on the local Y axis as local Y is determined by the location of the Head and Tail.

### **Rolling Shutter**

In real CMOS cameras the sensor is read out with scanlines and hence different scanlines are sampled at a different moment in time. This, for example, make vertical straight lines being curved when doing a horizontal camera pan. See also Rolling Shutter on Wikipedia.

### **Roughness Map**

A greyscale texture that defines how rough or smooth the surface of a material is. This may also be known as a Glossy Map.

### **Scanline**

Rendering technique. Much faster than ray tracing, but allows fewer effects, such as reflections, refractions, motion blur and focal blur.

### **Scene Referenced**

An image whose Luminance channel is not limited.

### **Shading**

Process of altering the color of an object/surface in the 3D scene, based on its angle to lights and its distance from lights to create a photo realistic effect.

### **Smoothing**

Defines how faces are shaded. Faces can be either solid (faces are rendered flat) or smooth (faces are smoothed by interpolating the normal on every point of the face).

### **Specular Light**

A light which is reflected precisely, like a mirror. Also used to refer to highlights on reflective objects.

### **SSS**

Subsurface Scattering. Mechanism of light transport in which light penetrates the surface of a translucent object, is scattered by interacting with the material, and exits the surface at a different point. All non-metallic materials are translucent to some degree. In particular, materials such as marble, skin, and milk are extremely difficult to simulate realistically without taking subsurface scattering into account.

### **Straight Alpha**

If an alpha channel is used in an image, there are two common representations that are available: straight (unassociated) alpha, and premultiplied (associated) alpha. With straight alpha, the RGB components represent the color of the object or pixel, disregarding its opacity. With premultiplied alpha, the RGB components represent the emission of the object or pixel, and the alpha represents the occlusion.

### **Subdiv / SDS**

Subdivision Surface. A method of creating smooth higher poly surfaces which can take a low polygon mesh as input.

### **Subdividing**

Technique for adding more geometry to a mesh. It creates new vertices on subdivided edges, new edges between subdivisions and new faces based on new edges. If new edges cross a new vertex is created at their crossing point.

### **Tail**

A sub component of a Bone. Has X, Y and Z coordinates measured in the Local Space of the Armature Object. Used in conjunction with the Head to define the local Y axis of a bone in Pose Mode. The smaller of the two ends when displayed as an Octahedron.

### **Tessellation**

The tiling of a plane using one or more geometric shapes usually resulting in Micro polygons.

### **Texture**

Specifies visual patterns on surfaces and simulates physical surface structure.

### **Texture Space**

The bounding box to use when using Generated mapping to add a Texture to an image.

### **Time code**

A coded signal on videotape or film giving information about the frame number and time the frame was recorded. Time codes are used to sync media between different recording devices, including both audio and video.

### **Title Safe**

Area of the screen visible on all devices. Place text and graphics inside this area to make sure they do not get cut off.

### **Topology**

The arrangement of Vertices, Edges, and Faces which define the shape of a mesh. See vertex, edge, and face.

### **Transforms**

The combined idea of location, rotation, and scale.

### **Triangle / Tri**

Face with exactly three vertices.

### **User**

The user for the current object.

### **UV Map**

Defines a relation between the surface of a mesh and a 2D texture. In detail, each face of the mesh is mapped to a corresponding face on the texture. It is possible and often common practice to map several faces of the mesh to the same or overlapping areas of the texture.

### **Vertex / Vertices**

A point in 3D space containing a location. It may also have a defined color. Vertices are the terminating points of edges.

### **Vertex Group**

Collection of vertices. Vertex groups are useful for limiting operations to specific areas of a mesh.

### **Voxel**

A cubic 3D equivalent to the square 2D pixel. The name is a combination of the terms “Volumetric” and “Pixel”. Used to store smoke and fire data from physics simulations.

### **Walk Cycle**

In animation, a walk cycle is a character that has just the walking function animated. Later on in the animation

process, the character is placed in an environment and the rest of the functions are animated.

### **Weight Painting**

Assigning vertices to a Vertex Group with a weight of 0.0 - 1.0.

### **White Point**

A reference value for white light defined by what happens when all the primaries, of the particular color model, are combined evenly.

A white point is defined by a set of CIE illuminates which correspond to a color temperature. For example, D65 corresponds to 6500K light, D70 corresponding to 7000K and so on.

### **World Space**

A 3D coordinate system that originates at a point at the origin of the world. Compare to Local Space.

### **Z-buffer**

Raster-based storage of the distance measurement between the camera and the surface points. Surface points which are in front of the camera have a positive Z value and points behind have negative values. The Z-depth map can be visualized as a greyscale image.

## 38 About this Manual

### Table of content

About this Manual.....	1
Manipulating Bforartists Manual.....	1
License.....	1

## About this Manual

Bforartists is a fork of the open source software Blender. And every software needs a manual. Bforartists 1 was equal enough to use the Blender manual in big parts for that. But even when the tools are the same than in Blender, the user interface differs quite a bit.

For Bforartists 2 we did a complete rewrite, and so this manual does not contain any parts from the Blender manual anymore.

## Editing the Bforartists Manual

The Bforartists Manual is a community driven effort to which anyone can contribute.

And this very easy, since the manual comes not only as PDF files, but also as editable \*.odt files. That's the file format for Libre and Open Office. Both free and open source Office solutions. To manipulate or to fix a typo, a word, a sentence or even a whole chapter is as easy as manipulating the text in Libre Office or Open Office, commit the changes to the manual repository, and tell the Bforartists developers to put it online.

The repository with the ODT files can be found here: <https://github.com/Bforartists/Manual>

## License

The Bforartists's Manual is free and published under Public Domain\*

This means that anyone is free to download, edit and share the manual. It also means that when contributing to the manual you don't hold exclusive copyright to your text. You are, of course, acknowledged and appreciated for your contribution. However others can change and improve your text in order to keep the manual consistent and up to date.

**\* As of writing this part here the Blender manual for 2.77 and below was put under a Public Domain AS CC0 license. Which is simply invalid. You can have either Public domain. Or CC0. Those two licenses contradicts each other.**

**It also seems that the Blender manual was put under CC0 and then once more under CC0 BY-SA without asking all involved persons if they wanted to do so. The original manual was under OCL license. Another license breach.**

**So we choose the license type that seems to fit most here, especially when looking at the old licensing. Public Domain. The old Blender parts are still under OCL license.**

**The Bforartists 2 manual should not contain any old Blender manual material anymore, and is fully licensed under Public Domain.**

## Bforartists 4 History

### Preface:

The Bforartists 4 release marks a milestone in the history of Bforartists, where for the first time, the project was presented at the Blender Conference 2023. This also marks the dawn of a development stage of creating asset presets and polish for various artists in a shifting landscape meanwhile keeping up with Blender development.

### History:

27.08.2024 – Bforartists 4.2.1 released.

30.07.2024 – Bforartists 4.2.0 released.

23.03.2024 – Bforartists 4.1.1 released.

01.04.2024 – Bforartists 4.1.0 released.

11.12.2023 – Bforartists 4.0.2 released.

18.11.2023 – Bforartists 4.0.1 released.

## Bforartists 3 History

### **Preface:**

The Bforartists 3 release marks another milestone in the history of Bforartists. There is nothing really special in feature terms. It's the permanent continued development and improvement as we do since years. Bit by bit. And improvement by improvement. A left aligned prop here, a new panel to improve usability there, and so on.

But with Blender 3 there is also a Bforartists version 3, with all the features from Blender 3.

Until Bforartists 3 we followed our own versioning. In the future we will try to stick as close as possible to the Blender versioning numbers. To make clear what Blender version is compatible with what Bforartists version, and vice versa. It can still happen though that this goes out of sync. In case we need to do a showstopper release for example. But the plan is to stick close.

With Bforartists 3 we also have reached a point where the manageable big development goals by us are all fulfilled. This means there won't be this massive changes to the UI anymore like in the past. It can still happen, but it is not the rule anymore. Bforartists was always in a productive state. But it now has finally reached a stable status in terms of feature completeness. So the main work in future versions is now to keep Bforartists up to date, and adjust it to the changes that comes in from Blender.

### **History:**

28.08.2023 – Bforartists 3.6.2 released.

07.08.2023 – Bforartists 3.6.1 released.

05.07.2023 – Bforartists 3.6.0 released.

08.05.2023 – Bforartists 3.5.1 released.

03.04.2023 – Bforartists 3.5.0 released.

10.01.2023 – Bforartists 3.4.1 released.

07.12.2022 – Bforartists 3.4.0 released.

12.10.2022 – Bforartists 3.3.1 released.

07.09.2022 – Bforartists 3.3.0 released.

08.08.2022 – Bforartists 3.2.2 released.

08.07.2022 – Bforartists 3.2.1 released.

09.06. 2022 - Bforartists 3.2.0 released.

09.04. 2022 - Bforartists 3.1.3 released. A hotfix release.

04.04. 2022 - Bforartists 3.1.2 released.

10.03. 2022 - Bforartists 3.1.0 released.

02.02. 2022 - Bforartists 3.0.1 released.

03.12.2021 - Bforartists 3.0.0 released.

## Bforartists 2 History

### **Preface:**

It was for a while not clear if and how we continue with the Bforartists 2 development. The Blender developers did quite a few things right with 2.80. Icon buttons in the tool shelf, streamlined UI and so on. In best case Blender 2.80 would have made a Bforartists 2 obsolete.

But they did from our point of view also quite a few things wrong again. The hard to read monochrome icons and still a hard to read standard theme, the new tool shelf, which is one gigantic hacky solution that doubles the tool set, still a big mess full of double menu entries, and so on. But alone the toolbar from Bforartists 1 justified the further development already. It is so useful. And so the decision was made to continue with development.

There was no exact date when the development started again. There was quite a few things still to do for Bforartists 1, which was at the same time preparation work for Bforartists 2 already. Manual for example. And the merge of Blender 2.80 code into the Bforartists master was also a longer process across several days. The official starting point was the release of the Bforartists 2 Manifest, which defines the will and the further development goals.

- Reiner

### **History:**

18.07.2021 - Bforartists 2.9.3 released.

01.07.2021 - Bforartists 2.9.2 released. A showstopper bug made a new version necessary.

25.06.2021 - Bforartists 2.9.1 released. This release ends the development cycle for Bforartists 2 in general.

11.06.2021 - Bforartists 2.9.0 released.

27.02.2021 - Bforartists 2.8.0 released.

26.01.2021 - Bforartists 2.7.0 released.

26.11.2020 - Bforartists 2.6.0 released.

24.09.2020 - Bforartists 2.5.1 released.

01.09.2020 - Bforartists 2.5.0 released.

03.07.2020 - Bforartists 2.4.0 released.

10.06.2020 - Bforartists 2.3.0 released.

26.05.2020 - Bforartists 2.2.0 released.

04.06.2020 - Bforartists 2.1.0 released.

18.04.2019 - Bforartists 2 Gold released. This release is the first productive version of Bforartists 2.

12.04.2019 - Bforartists 2 Release candidate released.

16.03.2020 - Bforartists 2 Beta 0.9.1 released. The first beta.

14.02.2020 - Bforartists 2 Alpha 0.9.0 released.

21.11.2019 - Bforartists 2 Alpha 0.8.0 released.

03.10.2019 - Bforartists 2 Alpha 0.7.0 released.

31.07.2019 - Bforartists 2 Alpha 0.6.0 released.

03.06.2019 - Bforartists 2 Alpha 0.5.0 released.

06.05.2019 - Bforartists 2 Alpha 0.4.0 released.

01.04.2019 - Bforartists 2 Alpha 0.3.0 released.

03.03.2019 - Bforartists 2 Alpha 0.2.0 released.

04.02.2019 - Bforartists 2 Alpha 0.1.0 released.

01.12.2018 - Merging Blender 2.80 into Bforartists Master.

27.10.2018 - Bforartists 2 Manifest released.

## Bforartists 1 History

### **Preface:**

Welcome to Bforartists, the free and open source 3D modeling, rendering and animation suite.

Bforartists is a fork of the popular open source 3d software Blender. And, similar to Blender, of course also open source and under the GPL license. The primary goal of the Bforartists fork is to deliver a better graphical UI and a better usability. This means a complete switch in the usage philosophy. Away from the hotkey and speed centered usage. Away from crazy decisions like RMB select. Towards a user friendly and intuitive graphical UI that can be used with a mouse and one hand when necessary. And that is much closer to the common UI standards of many other software.

The idea to solve the UI dilemma of Blender and to fork it was long around since years. It was no easy decision to really start it. Blender is a code monster. And so the answer to the question shall i really start a fork was always no. But at one point it was simply enough how the user interface got threaten by the Blender developers. The answer if Blender should be forked turned from \*no\* to \*possible with some big caveats\*. And then the decision was made to fork Blender.

The Bforartists project itself started officially at July the 2nd 2015. That's when the first real steps were done.

### **History:**

2.6.2015 - Decision day. The first pages for the UI proposal were written. The work at the homepage started.

Which was the official start of the whole project.

2.7.2015 - The domain bforartists was registered.

13.8.2015 - The Bforartists page was finished and went live.

22.8.2015 - GitHub account was created and went live.

21.9.2015 - The first Bforartists version 0.1 was released. It was based at Blender 2.75. And contained not this much more than the changed branding.

14.10.2015 - Version 0.2 brought the changes for Blender 2.76. And that was the moment when Bforartists started to walk alone.

19.12.2015 - Version 0.2.1 introduced a new key map and a new navigation scheme. And already quite a few changes at the UI layout. Blender has a ton of missing UI entries and a ton of double and even triple menu entries. It also brought in the Blender 2.76 a and b patches to Bforartists

27.01.2016 - Bforartists 0.2.2 was mainly around a plugin to display the most needed hotkeys up left.

18.03.2016 - Bforartists 0.3.0 introduced the first incarnation of icon buttons in the tool shelf.

26.03.2016 - Bforartists 0.3.1 came with some small fixes that were overlooked for version 0.3.0. The splash screen was changed because of ongoing trolling.

02.08.2016 - Bforartists 0.4.0 was a small refinement release that was the final stroke below the try to implement Qt and new editor types. Which did simply not work.

04.09.2016 - Bforartists 0.4.1 brought mainly changes to the tool tips. Nearly every tool tip contains the tool name now too.

16.09.2016 - 0.4.2 is another small release mainly around catching some more tool tips. and small quirks. New is the Materials Library FX add-on, which is also naively included into Blender 2.78 now.

24.09.2016 - 0.5.0 is a milestone release. It marks the end of the first big development cycle. The tracker is empty for the first time since development start.

02.11.2016 - 0.6.0 brings fixes to the addons, first sub tabs in the panels, and the Mini lightlib add-on.

01.12.2016 - 0.7.0 was mainly cleanup work in the Properties editor.

08.01.2017 - Version 0.8.0 brings the new Toolbar editor.

27.02.2017 - Version 0.9.0 is the merge of the actual Blender version 2.78 C into Bforartists.

13.03.2017 - Version 0.9.1 is a bug fix release that fixes some show stoppers from version 0.9.0.

10.4.2017 - Version 0.9.2 is around cleaning up the menus and connecting some loose ends. And it introduces a Mac build.

13.9.2017 - Version 0.9.3 is the merge of Blender 2.79 into Bforartists. Plus a few smaller adjustments and fixes.

14.9.2017 - An emergency release because of a showstopper bug. The bake panels were missing.

02.03.2018 - Version 0.9.6 brings the changes from Blender 2.79a, and adds 260 changes from Bforartists side.

19.04.2018 - Version 0.9.7 brings the full key map, the changes from Blender 2.79b, and lots of small improvements and fixes. More compact brush panels for example.

04.05.2018 - Version 1.0.0 RC1 marks the end of this development cycle. All initial development goals that could be fulfilled are fulfilled.

11.05.2018 - Version 1.0.0 is live.

## Blender's History

In 1988 Ton Roosendaal co-founded the Dutch animation studio NeoGeo. NeoGeo quickly became the largest 3D animation studio in the Netherlands and one of the leading animation houses in Europe. NeoGeo created award-winning productions (European Corporate Video Awards 1993 and 1995) for large corporate clients such as multi-national electronics company Philips. Within NeoGeo Ton was responsible for both art direction and internal software development. After careful deliberation Ton decided that the current in-house 3D toolset for NeoGeo was too old and cumbersome to maintain, and needed to be rewritten from scratch. In 1995 this rewrite began and was destined to become the 3D software creation we all know as Blender. As NeoGeo continued to refine and improve Blender it became apparent to Ton that Blender could be used as a tool for other artists outside of NeoGeo.

In 1998, Ton decided to found a new company called Not a Number (NaN) as a spin-off of NeoGeo to further market and develop Blender. At the core of NaN was a desire to create and distribute a compact, cross platform 3D application for free. At the time this was a revolutionary concept as most commercial 3D applications cost thousands of dollars. NaN hoped to bring professional level 3D modeling and animation tools within the reach of the general computing public. NaN's business model involved providing commercial products and services around Blender. In 1999 NaN attended its first SIGGRAPH conference in an effort to more widely promote Blender. Blender's first SIGGRAPH convention was a huge success and gathered a tremendous amount of interest from both the press and attendees. Blender was a hit and its huge potential confirmed!

Following the success of the SIGGRAPH conference in early 2000, NaN secured financing of €4.5M from venture capitalists. This large inflow of cash enabled NaN to rapidly expand its operations. Soon NaN boasted as many as fifty employees working around the world trying to improve and promote Blender. In the summer of 2000, Blender 2.0 was released. This version of Blender added the integration of a game engine to the 3D application. By the end of 2000, the number of users registered on the NaN website surpassed 250,000.

Unfortunately, NaN's ambitions and opportunities didn't match the company's capabilities and the market realities of the time. This over-extension resulted in restarting NaN with new investor funding and a smaller company in April 2001. Six months later NaN's first commercial software product, Blender Publisher was launched. This product was targeted at the emerging market of interactive web-based 3D media. Due to disappointing sales and the ongoing difficult economic climate, the new investors decided to shut down all NaN operations. The shutdown also included discontinuing the development of Blender. Although there were clearly shortcomings in the then current version of Blender, such as a complex internal software architecture, unfinished features and a non-standard way of providing the GUI, the enthusiastic support from the user community and customers who had purchased Blender Publisher in the past meant that Ton couldn't justify leaving Blender to fade into insignificance. Since restarting a company with a sufficiently large team of

developers wasn't feasible, Ton Roosendaal founded the non-profit organization Blender Foundation in March 2002.

The Blender Foundation's primary goal was to find a way to continue developing and promoting Blender as a community-based open source project. In July 2002, Ton managed to get the NaN investors to agree to a unique Blender Foundation plan to attempt to release Blender as open source. The "Free Blender" campaign sought to raise €100,000 so that the Foundation could buy the rights to the Blender source code and intellectual property rights from the NaN investors and subsequently release Blender to the open source community. With an enthusiastic group of volunteers, among them several ex-NaN employees, a fund raising campaign was launched to "Free Blender". To everyone's surprise and delight the campaign reached the €100,000 goal in only seven short weeks. On Sunday October 13, 2002, Blender was released to the world under the terms of the GNU GPL. Blender development continues to this day driven by a team of dedicated volunteers from around the world led by Blender's original creator, Ton Roosendaal.

## Video: From Blender 1.60 to 2.50

<https://vimeo.com/8567074>

## Version/Revision Milestones

### The start!

- 1.00 - January 1994: Blender in development at animation studio NeoGeo.
- 1.23 - January 1998: SGI version published on the web, IrisGL.
- 1.30 - April 1998: Linux and FreeBSD version, port to OpenGL and X11.
- 1.3x - June 1998: NaN founded.
- 1.4x - September 1998: Sun and Linux Alpha version released.
- 1.50 - November 1998: First Manual published.
- 1.60 - April 1999: C-key (new features behind a lock, \$95), MS-Windows version released.
- 1.6x - June 1999: BeOS and PPC version released.
- 1.80 - June 2000: End of C-key, Blender full freeware again.
- 2.00 - August 2000: Interactive 3D and real-time engine.
- 2.10 - December 2000: New engine, physics, and Python.
- 2.20 - August 2001: Character animation system.
- 2.21 - October 2001: Blender Publisher launch.
- 2.2x - December 2001: Mac OSX version.

### Blender goes Open Source

- **13 October 2002: Blender goes Open Source, 1st Blender Conference.**
- 2.25 - October 2002: Blender Publisher becomes freely available.
- Tuhopuu1 - Oct 2002: The experimental tree of Blender is created, a coder's playground.
- 2.26 - February 2003: The first true open source Blender release.
- 2.27 - May 2003: The second open source Blender release.
- 2.28x - July 2003: First of the 2.28x series.

- 2.30 - October 2003: Preview release of the 2.3x UI makeover presented at the 2nd Blender Conference.
- 2.31 - December 2003: Upgrade to stable 2.3x UI project.
- 2.32 - January 2004: Major overhaul of internal rendering capabilities.
- 2.33 - April 2004: Game Engine returns, ambient occlusion, new procedural textures.
- 2.34 - August 2004: Particle interactions, LSCM UV mapping, functional YafRay integration, weighted creases in subdivision surfaces, ramp shaders, full OSA, and many many more.
- 2.35 - November 2004: Another version full of improvements: object hooks, curve deforms and curve tapers, particle duplicators and much more.
- 2.36 - December 2004: A stabilization version, much work behind the scene, normal and displacement mapping improvements.
- 2.37 - June 2005: Transformation tools and widgets, softbodies, force fields, deflections, incremental subdivision surfaces, transparent shadows, and multi-threaded rendering.
- 2.40 - December 2005: Full rework of armature system, shape keys, fur with particles, fluids and rigid bodies.
- 2.41 - January 2006: Lots of fixes, and some game engine features.
- 2.42 - July 2006: The nodes release, array modifier, vector blur, new physics engine, rendering, lip sync, and many other features. This was the release following Project Orange.
- 2.43 - February 2007: Multi-resolution meshes, multi-layer UV textures, multi-layer images and multi-pass rendering and baking, sculpting, retopology, multiple additional matte, distort and filter nodes, modeling and animation improvements, better painting with multiple brushes, fluid particles, proxy objects, sequencer rewrite, and post-production UV texturing.
- 2.44 - May 2007: The big news, in addition to two new modifiers and re-awakening the 64-bit OS support, was the addition of subsurface scattering, which simulates light scattering beneath the surface of organic and soft objects.
- 2.45 - September 2007: Serious bug fixes, with some performance issues addressed.
- 2.46 - May 2008: The Peach release was the result of a huge effort of over 70 developers providing enhancements to provide hair and fur, a new particle system, enhanced image browsing, cloth, a seamless and non-intrusive physics cache, rendering improvements in reflections, AO, and render baking, a mesh deform modifier for muscles and such, better animation support via armature tools and drawing, skinning, constraints and a colorful Action Editor, and much more. It was the release following Project Peach.
- 2.47 - August 2008: Bugfix release.
- 2.48 - October 2008: The Apricot release, cool GLSL shaders, lights and GE improvements, snap, sky simulator, shrinkwrap modifier, and Python editing improvements. This was the release following Project Apricot.
- 2.49 - June 2009: Node-based textures, armature sketching (called Etch-a-Ton), boolean mesh operation improvements, JPEG2000 support, projection painting for direct transfer of images to models, and a significant Python script catalogue. GE enhancements included video textures, where you can play movies in-game, upgrades to the Bullet physics engine, dome (fish-eye) rendering, and more API GE calls made available.

## **Blender 2.5x - The Recode!**

- 2.5x - From 2009 to August 2011: This series released four pre-version (from Alpha 0 in November 2009 to Beta in July 2010) and three stable versions (from 2.57 - April 2011 - to 2.59 - August 2011). It

is one of the most important development projects, with a total refactor of the software with new functions, redesign of the internal window manager and event/tool/data handling system, and new Python API. The final version of this project was Blender 2.59 in August 2011.

## Blender 2.6x to 2.7x - Improvements & Stabalizing

- 2.60 - October 2011: Internationalization of the UI, improvements in animation system and the GE, vertex weight groups modifiers, 3D audio and video, bug fixes, and the UI internationalization.
- 2.61 - December 2011: The Cycles renderer was added in trunk, the camera tracker was added, dynamic paint for modifying textures with mesh contact/approximation, the Ocean Sim modifier to simulate ocean and foam, new add-ons, bug fixes, and more extensions added for the Python API.
- 2.62 - February 2012: The Carve library was added to improve boolean operations, support for object tracking was added, the Remesh modifier was added, many improvements in the GE, matrices and vectors in the Python API were improved, new add-ons, and many bug fixes.
- 2.63 - April 2012: Bmesh was merged to trunk with full support for n-sided polygons, sculpt hiding, a panoramic camera for Cycles, mirror ball environment textures and float precision textures, render layer mask layers, ambient occlusion and viewport display of background images and render layers, new import and export add-ons were added, and 150 bug fixes.
- 2.64 - October 2012: Mask editor, improved motion tracker, OpenColorIO, Cycles improvements, sequencer improvements, better mesh tools (Inset and Bevel were improved), new keying nodes, sculpt masking, Collada improvements, new skin modifier, new compositing nodes backend, and many bugs were fixed.
- 2.65 - December 2012: Fire and smoke improvements, anisotropic shader for Cycles, modifier improvements, bevel tool now includes rounding, new add-ons, and over 200 bug fixes.
- 2.66 - February 2013: Dynamic topology, rigid body simulation, improvements in UI and usability (including retina display support), Cycles now supports hair, the bevel tool now supports individual vertex bevelling, new *Mesh Cache* modifier and the new *UV Warp* modifier, new SPH particle fluid solver. More than 250 bug fixes.
- 2.67 - May 2013: Freestyle was added, paint system improvements, subsurface scattering for Cycles, Ceres library in the motion tracker, new custom python nodes, new mesh modeling tools, better support for UTF8 text and improvements in text editors, new add-ons for 3D printing, over 260 bug fixes.
- 2.68 - July 2013: New and improved modeling tools, three new Cycles nodes, big improvements in the motion tracker, Python scripts and drivers are disabled by default when loading files for security reasons, and over 280 bug fixes.
- 2.69 - October 2013: Even more modeling tools, Cycles improved in many areas, plane tracking is added to the motion tracker, better support for FBX import/export, and over 270 bugs fixed.
- 2.70 - March 2014: Cycles gets basic volumetric support on the CPU, more improvements to the motion tracker, two new modeling modifiers, some UI consistency improvements, and more than 560 bug fixes.
- 2.71 - June 2014: Deformation motion blur and fire/smoke support is added to Cycles, UI popups are now draggable, performance optimizations for sculpting mode, new interpolation types for animation, many improvements to the GE, and over 400 bug fixes.
- 2.72 - October 2014: Cycles gets volume and SSS support on the GPU, pie menus are added and tooltips greatly improved, the intersection modeling tool is added, new sun beam node for the compositor, Freestyle now works with Cycles, texture painting workflow is improved, and more than 220 bug fixes.
- 2.73 - January 2015: Cycles gets improved volumetric support, major upgrade to grease pencil, MS-

Windows gets Input Method Editors (IMEs) and general improvements to painting, freestyle, sequencer and add-ons.

- 2.74 - March 2015: Support for custom-normals, viewport compositing and improvements to hair dynamics.
- 2.75 - July 2015: Integrated stereo/multi-view pipeline, corrective smooth modifier and new dependency graph (*enable as a command line option*).
- 2.76 - November 2015: Pixar OpenSubdiv support, Viewport and File Browser performance boost, node auto-offset, and a text effect strip for the Sequencer.

## About Free Software and the GPL

When one hears about “free software”, the first thing that comes to mind might be “no cost”. While this is typically true, the term “free software” as used by the Free Software Foundation (originators of the GNU Project and creators of the GNU General Public License) is intended to mean “free as in freedom” rather than the “no cost” sense (which is usually referred to as “free as in free beer” or *gratis*). Free software in this sense is software which you are free to use, copy, modify, redistribute, with no limit. Contrast this with the licensing of most commercial software packages, where you are allowed to load the software on a single computer, are allowed to make no copies, and never see the source code. Free software allows incredible freedom to the end user. Since the source code is universally available, there are also many more chances for bugs to be caught and fixed.

When a program is licensed under the GNU General Public License (the GPL):

- You have the right to use the program for any purpose.
- You have the right to modify the program, and have access to the source codes.
- You have the right to copy and distribute the program.
- You have the right to improve the program, and release your own versions.

In return for these rights, you have some responsibilities if you distribute a GPL'd program, responsibilities that are designed to protect your freedoms and the freedoms of others:

- You must provide a copy of the GPL with the program, so that recipients are aware of their rights under the license.
- You must include the source code or make the source code freely available.
- If you modify the code and distribute the modified version, you must license your modifications available under the GPL (or a compatible license).
- You may not restrict the licensing of the program beyond the terms of the GPL. (you may not turn a GPL'd program into a proprietary product.)

For more on the GPL, check the its page on the GNU Project web site.

Note

The GPL only applies to the Bforartists application and **not** the artwork you create with it; for more info see the Bforartists or Blender License.

## 40 - Manual Update History

- 27.08.2024 – Updated the manula to Bforartists 4 version 4.2.1
- 23.08.2024 – Updated the manula to Bforartists 4 version 4.2.0
- 23.04.2024 – Updated the manula to Bforartists 4 version 4.1.1
- 01.04.2024 – Updated the manula to Bforartists 4 version 4.1.0
- 11.12.2023 – Updated the manula to Bforartists 4 version 4.0.2
- 18.11.2023 – Updated the manula to Bforartists 4 version 4.0.1
- 29.08.2023 - Updated the manual to Bforartists 3 version 3.6.2
- 05.08.2023 - Updated the manual to Bforartists 3 version 3.6.1
- 05.07.2023 - Updated the manual to Bforartists 3 version 3.6.0
- 08.05.2023 - Updated the manual to Bforartists 3 version 3.5.1
- 03.04.2023 - Updated the manual to Bforartists 3 version 3.5.0
- 11.01.2023 - Updated the manual to Bforartists 3 version 3.4.1
- 08.12.2022 - Updated the manual to Bforartists 3 version 3.4.0
- 12.10.2022 - Updated the manual to Bforartists 3 version 3.3.1
- 18.09.2022 - Updated the manual to Bforartists 3 version 3.3.0
- 08.08.2022 - Updated the manual to Bforartists 3 version 3.2.2
- 08.07.2022 - Updated the manual to Bforartists 3 version 3.2.1
- 09.06.2022 - Updated the manual to Bforartists 3 version 3.2.0
- 09.04.2022 - Updated the manual to Bforartists 3 version 3.1.3
- 04.04.2022 - Updated the manual to Bforartists 3 version 3.1.2
- 10.03.2022 - Updated the manual to Bforartists 3 version 3.1.0
- 02.02.2022 - Updated the manual to Bforartists 3 version 3.0.1
- 30.11.2021 - Updated the manual to Bforartists 3 version 3.0.0
- 18.07.2021 - Updated the manual to Bforartists 2 version 2.9.3
- 01.07.2021 - Updated the manual to Bforartists 2 version 2.9.2
- 25.06.2021 - Updated the manual to Bforartists 2 version 2.9.1
- 10.06.2021 - Updated the manual to Bforartists 2 version 2.9.0
- 27.02.2021 - Updated the manual to Bforartists 2 version 2.8.0
- 26.01.2021 - Updated the manual to Bforartists 2 version 2.7.0

27.11.2020 - Updated the manual to Bforartists 2 version 2.6.0

24.09.2020 - Updated the manual to Bforartists 2 version 2.5.1

01.09.2020 - Updated the manual to Bforartists 2 version 2.5.0

31.08.2020 - Cleanup and spell checking.

28.08.2020 - Improved chapter 7.3.6 Editors - 3D View - Sidebar - Tool Tab - Mesh - Sculpt Mode

27.08.2020 - Updated the manual to Bforartists 2 version 2.5.0

24.08.2020 - Added chapters 13 around video editing

17.08.2020 - Added chapter 25.10.6 + 25.10.7 + 25.10.8

13.08.2020 - Added chapter 25.10.4 + 25.10.5

11.08.2020 - Added chapter 25.10.3

10.08.2020 - Added chapter 25.10.2

08.08.2020 - Added chapter 25.10 and 25.10.1

07.08.2020 - Added chapters around 25.9, Particles tab

04.08.2020 - Updated manual to Bforartists 2.4.0

30.07.2020 - Added chapter 25.14 Editors - Properties Editor - Texture Tab.pdf

29.07.2020 - Added chapter 25.13 Editors - Properties Editor - Materials Tab.pdf

28.07.2020 - UV Editor , added chapters 25.12 around the object data tab

22.07.2020 - UV Editor , added documentation for UDIM

18.07.2020 - Small additions and corrections. Added chapter 25.12 and 7.3.15

14.07.2020 - Updated the manual to the latest changes of Bforartists 2.3.0

12.07.2020 - Added chapter 25.8.4 and 25.8.5

09.07.2020 – Added chapter 25.8.3

06.07.2020 – Added chapter 25.8.1 and 25.8.2

03.07.2020 - Added chapter 25.8 Editors - Properties Editor - Modifiers Tab.odt, Update chapter 7.2.2

01.07.2020 - Added chapter 25.11 Editors - Properties Editor - Object Constraints Tab

30.06.2020 - Updated chapter 25.7

29.06.2020 - Updated chapters 12, 20 and 25.4, added chapter 25.5

28.06.2020 - Updated the manual to the changes of Bforartists, splitted chapter 5 into sub chapters, added chapter 25.6 Editors - Properties Editor - World Tab

25.06.2020 - Added chapter 25.3 Editors - Properties Editor - Output Tab

21.06.2020 - Added chapters 19 around NLA editor

- 17.06.2020 - Added chapters 7.0.x around the 3D view context menus
- 12.06.2020 - Updated chapter 36 Standard Keymap
- 10.06.2020 - Updated chapter 33 Glossary
- 09.06.2020 - Reordered some chapters, added some missing information
- 09.06.2020 - Removed lots of "Here you can" phrases
- 07.06.2020 - Added chapters 18 around Drivers Editor
- 29.05.2020 - Manual update for upcoming Bforartists 2.1.0 version
- 28.05.2020 - Manual update for upcoming Bforartists 2.1.0 version
- 01.06.2020 - Added chapters 17 around Graph Editor
- 28.05.2020 - Manual update for upcoming Bforartists 2.1.0 version
- 25.05.2020 - Added chapters 16 around the Timeline
- 23.05.2020 - Updated chapters to new sculpting feature Draw Face Sets
- 22.05.2020 - Updated chapter 2 Keymap
- 20.05.2020 - Manual update for upcoming Bforartists 2.1.0 version, changed order of chapters in chapter 8 and 9.
- 16.05.2020 - Added chapters 15 around the dope sheet editor

- 19.02.2020 - Updated the manual to the latest changes for the Bforartists 2 Alpha 0.9.0 release
- 13.02.2020 - updated chapters 7.3.6 Editors - 3D View - Sidebar - Tool Tab - Sculpt Mode, 7.3.7 Editors - 3D View - Sidebar - Tool Tab - Vertex Paint Mode, 7.3.8 Editors - 3D View - Sidebar - Tool Tab - Weight Paint Mode, 7.3.9 Editors - 3D View - Sidebar - Tool Tab - Texture Paint Mode and 8.3.1 Editors - Image Editor - Sidebar - Tools Tab in Paint Mode
- 04.02.2020 - added chapter 10 Editors - Shader Editor.pdf
- 01.02.2020 - moved the chapters properties - tools tab to 3d view - tools tab

23.01.2020 - added chapter 9.3 Editors - UV Editor - Sidebar.pdf, 9.3.1 Editors - UV Editor - Sidebar - Image Tab.pdf, 9.3.2 Editors - UV Editor - Sidebar - Tools Tab.pdf and 9.3.3 Editors - UV Editor - Sidebar - View Tab.pdf

01.01.2020 - reorganized chapter 7.1 and 7.2

29.12.2019 - updated chapter 1 Installing Bforartists.pdf

29.12.2019 - added chapter 9.1.5 Editors - UV Editor - Header - Header Tools.pdf

20.12.2019 - added chapter 9.1.4 Editors - UV Editor - Header - UV menu.pdf

18.12.2019 - added chapter 9.1.3 Editors - UV Editor - Header - Image Menu.pdf

17.12.2019 - added chapter 9.1.2 Editors - UV Editor - Header - Select Menu.pdf

16.12.2019 - added chapter 9 Editors - UV Editor.pdf, 9.1 Editors - UV Editor - Header.pdf, 9.1.1 Editors - UV Editor - Header - View Menu.pdf

12.12.2019 - added chapter 8.3.3 Editors - Image Editor - Sidebar - View Tab.pdf, 8.3.4 Editors - Image Editor - Sidebar - Scopes Tab.pdf and 8.3.5 Editors - Image Editor - Sidebar - Mask Tab.pdf

09.12.2019 - added chapter 8.3.2 Editors - Image Editor - Sidebar - Image Tab.pdf

28.11.2019 - added chapter 8.1.7 Editors - Image Editor - Tool Shelf.pdf

20.11.2019 - added chapter 8.1.3 Editors - Image Editor - Header - Select menu, 8.1.4 Editors - Image Editor - Header - Add menu, 8.1.5 Editors - Image Editor - Header - Mask menu, 8.1.6 Editors - Image Editor - Header - Header Tools.pdf

18.11.2019 - added chapter 8.1.2 Editors - Image Editor - Header - Image menu.pdf

17.11.2019 - small changes at chapter 7.2, 7.23 and 8, added 8.1 Editors - Image Editor - Header.pdf and 8.1.1 Editors - Image Editor - Header - View menu.pdf

16.11.2019 - added chapter 8 Editors - Image Editor.pdf, Update chapter 6 Editors introduction.pdf

15.11.2019 - added chapter 7.3.1 Editors - 3D View - Sidebar - Mini Lightlib.pdf

14.11.2019 - added chapter 7.3 Editors - 3D View - Sidebar.pdf

11.11.2019 - added brush menu to chapters 7.2, renamed chapters

10.11.2019 - Added chapter 7.1.15 Editors - 3D View - Tool Shelf - Grease Pencil - Weight Paint Mode and 7.1.16 Editors - 3D View - Tool Shelf - Armature - Edit Mode.pdf and 7.1.17 Editors - 3D View - Tool Shelf - Armature - Pose Mode.pdf and 7.1.18 Editors - 3D View - Tool Shelf - Lattice - Edit Mode.pdf

09.11.2019 - Added chapter 7.1.14 Editors - 3D View - Tool Shelf - Grease Pencil - Draw Mode

08.11.2019 - Added chapter 7.1.13 Editors - 3D View - Tool Shelf - Grase Pencil - Sculpt Mode.pdf

06.11.2019 - Added chapter 7.1.11 Editors - 3D View - Tool Shelf - Text - Edit Mode.pdf, 7.1.12 Editors - 3D View - Tool Shelf - Grase Pencil - Edit Mode.pdf

05.11.2019 - Added chapter 7.1.9 Editors - 3D View - Tool Shelf - Surface - Edit Mode, 7.1.10 Editors - 3D View - Tool Shelf - Metaball - Edit Mode

- 04.11.2019 - Added chapter 7.1.7 Editors - 3D View - Tool Shelf - Mesh - Particle Edit Mode.pdf and 7.1.8 Editors - 3D View - Tool Shelf - Curve - Edit Mode.pdf, small fixes
- 31.10.2019 - Added chapter 7.1.6 Editors - 3D View - Tool Shelf - Mesh - Textute Paint Mode.pdf
- 30.10.2019 - Added chapter 7.1.5 Editors - 3D View - Tool Shelf - Mesh - Weight Paint Mode.pdf
- 29.10.2019 - Added chapter 7.1.4 Editors - 3D View - Tool Shelf - Mesh - Vertex Paint Mode.pdf
- 28.10.2019 - Added chapter 7.1.3 Editors - 3D View - Tool Shelf - Mesh - Sculpt Mode.pdf
- 27.10.2019 - Updated chapter 25.1.3 Editors - Properties Editor - Tools Tab - Sculpt Mode.odt
- 26.10.2019 - Added chapter 7.1.2 Editors - 3D View - Tool Shelf - Mesh - Edit Mode.pdf
- 22.10.2019 - Added chapter 7.1.1 Editors - 3D View - Tool Shelf - Object Mode.pdf
- 18.10.2019 - Added chapter 7.1 Editors - 3D View - Tool Shelf.pdf
- 16.10.2019 - Reordered the header menu chapters in the 3d view.
- 15.10.2019 - Added chapter 7.2.8.15 Editors - 3D View - Header - Grease Pencil - Draw mode - Draw menu.pdf and 7.2.8.15 Editors - 3D View - Header - Grease Pencil - Weight Paint Mode - Weights Menu.pdf
- 13.10.2019 - Added chapter 7.2.14 Editors - 3D View - Header - Armature - Pose mode - Pose menu.pdf
- 09.10.2019 - Added chapter 7.2.12 Editors - 3D View - Header - Particle - Particle mode - Particle menu.pdf
- 08.10.2019 - Added chapter 7.2.11 Editors - 3D View - Header - Mesh - Weight Paint mode - Weight menu.pdf
- 07.10.2019 - Added chapter 7.2.9 Editors - 3D View - Header - Mesh - Sculpt mode - Sculpt menu.pdf and 7.2.9.1 Editors - 3D View - Header - Mesh - Sculpt mode - Mask menu.pdf and 7.2.10 Editors - 3D View - Header - Mesh - Vertex Paint mode - Paint menu.pdf
- 06.10.2019 - Added chapter 7.2.8.17 Editors - 3D View - Header - Armature - Edit mode - Armature menu.pdf, 7.2.8.18 Editors - 3D View - Header - Lattice - Edit mode - Lattice menu.pdf
- 05.10.2019 - Update the manual to the changes of Bforartists 0.7.0 #141
- 30.09.2019 - Added chapter 7.2.8.15 Editors - 3D View - Header - Grease Pencil - Edit mode - Stroke menu.pdf, added chapter 7.2.8.16 Editors - 3D View - Header - Grease Pencil - Edit mode - Points menu.pdf
- 27.09.2019 - Added chapter 7.2.8.14 Editors - 3D View - Header - Grease Pencil - Edit mode - Grease Pencil menu.pdf
- 23.09.2019 - Added chapter 7.2.8.13 Editors - 3D View - Header - Text - Edit mode - Font menu.pdf
- 22.09.2019 - Added chapter 7.2.8.12 Editors - 3D View - Header - Text - Edit mode - Edit menu.pdf
- 21.09.2019 - Fixes at chapter 7.2.8.8 and 7.2.8.9, added chapter 7.2.8.10 Editors - 3D View - Header - Surface - Edit mode - Surface menu, added 7.2.8.11 Editors - 3D View - Header - Metaball - Edit mode - Metaball menu.pdf
- 20.09.2019 - Added chapter 7.2.8.8 Editors - 3D View - Header - Edit mode - Control points menu.pdf, 7.2.8.9 Editors - 3D View - Header - Curve - Edit mode - Segments menu.pdf, renamed chapter 7.2.8.2 up to 7.2.8.8
- 19.09.2019 - Added chapter 7.2.8.7 Editors - 3D View - Header - Edit mode - Curve menu.pdf

18.09.2019 - Added chapter 7.2.8.6 Editors - 3D View - Header - Edit mode - UV menu.pdf  
17.09.2019 - Added chapter 7.2.8.5 Editors - 3D View - Header - Edit mode - Faces menu.pdf  
16.09.2019 - Added chapter 7.2.8.4 Editors - 3D View - Header - Edit mode - Edge Menu.pdf  
15.09.2019 - Added chapter 7.2.8.3 Editors - 3D View - Header - Edit Mode - Vertex Menu.pdf  
13.09.2019 - Added chapter 7.2.8.2 Editors - 3D View - Header - Edit mode - Mesh menu.pdf  
05.09.2019 - Updated chapter 7.2.8.1 Editors - 3D View - Header - Edit mode - Add menu. Small fixes at 7.2.7 Editors - 3D View - Header - Object menu and 35 Bforartists History  
03.09.2019 - Updated chapter 24 Editors - Outliner  
02.09.2019 - Added chapter 7.2.7 Editors - 3D View - Header - Object menu  
23.08.2019 - Added chapter 7.2.6 Editors - 3D View - Header - Add Menu  
23.08.2019 - Added chapter 7.2.5 Editors - 3D View - Header - Select Menu  
18.08.2019 - Added chapter 7.2.4 Editors - 3D View - Header - Navigation Menu  
17.08.2019 - Added chapter 7.2.3 Editors - 3D View - Header - View Menu  
16.08.2019 - Added chapter 7.2.2 Editors - 3D View - Header - Quick Menu  
15.08.2019 - Added chapter 7.2.1 Editors - 3D View - Header tools and Options  
25.07.2019 - Update chapter 7.2 Editors - 3D View - Header to BFA 2#63  
22.07.2019 - Update chapter 7 Editors - 3D View to BFA 2 #61  
19.07.2019 - Update chapter 25.2 Editors - Properties Editor - Render Tab to BFA 2 #98  
12.07.2019 - Rework chapter 25.1 to 25.1.8 #137  
07.07.2019 - Added chapter 25.16 Editors - Properties Editor - Bone Constraints  
05.07.2019 - Updated chapter 27 Editors - Preferences  
02.07.2019 - Updated chapter 2 - Standard Keymap  
22.05.2019 - Added chapter 27 Editors - Preferences  
16.05.2019 - Updated the chapters 2, 23, 24, 25 to fit to Bforartists 0.4.0 release

## Introduction

The interaction concept for Bforartists is the graphical UI. And so the Bforartists key map is as reduced as possible. It still contains most of the standard navigation hotkeys, and also standard hotkeys like for copy and paste, but many hotkeys for tools are removed. So that users can implement their own hotkeys how they need it and when they need it.

The key map that you can find in the Input Manager in the User Preferences is nevertheless still pretty heavy as you can see here. That's because the Input Manager in the user preferences contains all available user interaction. And not just the usual hotkeys to call tools like in other software. There is no distinction between tools and things like editor manipulation. Every user interaction is defined here. So be careful what you change at the here listed input nodes. You may remove a vital part to deal with windows for example.

The hotkeys are also editor specific. So there are lots of repetitions when you need the same hotkeys across several editors too. Navigation hotkeys for example exists in all editor sub categories.

The key manager is divided into categories. And this part of the manual follows the same structure.

### Legend

- press = press and hold
- click = press and release
- dbl- = Double tap. You need to press this key twice.
- release = run when releasing from a press, eg. mouse up
- click-drag = press and hold and move mouse, eg. clicking and dragging

Most hotkeys are set to “press”  
 N dof hotkeys are for tablet or 3d mouse.

**Note:** *Some hotkeys are used in more than one menu. That's for example the case for hotkeys in the Node Editor section. They are true in three different editors, Shader Editor, Compositor, and Texture Node Editor. To make it even worse, some exists in just one editor, and in a special mode.*

### For Mac OS users

When a hotkey is listed with “Ctrl”, this will mean the keyboard “Option” key.

## Window

### Window

Name	Function	Menu location	Hotkey
------	----------	---------------	--------

<b>Window</b>			
Reload Startup File	Creates a new scene	Header / New	Ctrl N
Open Blender File	Open Blender file	Header / Open	Ctrl O
Save Blender File	Save Blender File	Header / Save	Ctrl S
Save As Blender File	Save As Blender File	Header / Save as	Shift Ctrl S
Call Menu	Calls the Quick Favorites menu	No Location	Q
Call Menu	Ndof device for 3dConnexion	No Location	Ndof Menu
Context Scale Float	Ndof device for 3dConnexion	No Location	Ndof Plus
Context Scale Float	Ndof device for 3dConnexion	No Location	Ndof Minus
Context Scale Float	Ndof device for 3dConnexion	No Location	Shift Ndof Plus
Context Scale Float	Ndof device for 3dConnexion	No Location	Shift Ndof Minus
Update Reports Display	Unknown	No Location	Timer Report
Search Menu	Search Menu	Header / Edit Menu / Operator Search	F3
Toggle System Console	Toggles System Console - Windows only, makes problems on Linux.	Header / Window Menu / Toggle System Console	Alt F5
Call Menu	Calls the file context menu	None	F4
Rename Active Item	Calls a menu to rename the selected item	None	F2
Batch Rename	Batch rename of selected items	None	Ctrl F2

## Screen

<b>Screen / Screen (Global)</b>			
Name	Function	Surface menu location	Hotkey
Animation Step	Unknown	No Location	Timer 0
Region Alpha	Unknown	No Location	Timer Region
Toggle Maximize Area	Toggles the current selected editor between Fullscreen and Windowed. WITHOUT menus	Right Mouse menu of the menu bars	Ctrl Spacebar
Toggle Maximize Area	Toggles the current selected editor between Fullscreen and Windowed. WITHOUT menus	Right Mouse menu of the menu bars	Ctrl Alt Spacebar
Cycle Space Context	Calls a pie menu to switch between modes.	None	Ctrl Tab
Cycle Workspace	Cycle through the workspaces	None	Ctrl Page Up
Cycle Workspace	Cycle through the workspaces	None	Ctrl Page Down
Toggle Quad View	Toggle Quad View	3D View / View Menu / Area Menu / Toggle Quad View	Ctrl Alt Q
Execute File Window	Execute. Like entering a value, then press enter....	None	Return
Execute File Window	Execute. Like entering a value, then press enter....	None	Numpad Enter
Cancel File load	Cancel file load	None	Esc
Undo	Undo	Sometimes in Object menu, sometimes in Edit menu. Also in 3D View Tool shelf / History	Ctrl Z

<b>Screen / Screen (Global)</b>			
Redo	Redo Sometimes in Object menu, sometimes in Edit menu. Also in 3D View Tool shelf / History	Sometimes in Object menu, sometimes in Edit menu. Also in 3D View Tool shelf / History	Shift Ctrl Z
Render Image / Animation	Render a single image	Info Editor / Render / Render Image	F12
Render Image / Animation	Render animation sequence	Info Editor / Render / Render Animation	Ctrl F12
Cancel Render View	Escapes the Render View	No Menu entry	Esc
Show / Hide Render View	Show / Hide Render View	Header / Render / Show / Hide Render View	F11
Play Rendered Animation	Play	Header / Render menu / View Animation	Ctrl F11
Flip Region	flips tool shelf or sidebar to the other side	None	F5
Redo Last	Calls the adjust last operation panel under the mouse	If available down left. Also in the toolbar.	F6
Undo	Undo of the last operation in asset manager	Edit menu	Ctrl Z
Redo	Redo of the last operation in asset manager	Edit menu	Shift Ctrl Z

<b>Screen /Screen Editing</b>			
Name	Function	Surface menu location	Hotkey
Handle Area Action Zones	Split / Join window code. Needed for Move Area edges and Area Options	None	Left Mouse
Handle Area Action Zones	Make new floating window. First part. You need both parts.	None	Shift Left Mouse
Handle Area Action Zones	Drag into other editor window to swap position with it. First part. You need both parts.	None	Left Mouse
Handle Area Action Zones	Drag into other editor window to swap position with it. First part. You need both parts.	None	Shift Left Mouse
Handle Area Action Zones	Drag into other editor window to swap position with it. First part. You need both parts.	None	Ctrl Left Mouse
Split area	Split Area code	None	Action Zone Area
Join Area	Join Area code	None	Action Zone Area
Duplicate Area into new Window	Make new floating window. Second part. You need both parts.	None	Shift Action Zone Area
Swap Areas	Drag into other editor window to swap position with it. Second part. You need both parts.	None	Ctrl Action Zone Area
Scale Region Size	Scale Region Size	None	Action Zone Region
Toggle Fullscreen Area	Toggle Fullscreen Area	None	Action Zone Fullscreen
Move Area Edges	Split Windows	None	Left Mouse
Area Options	Join Windows	None	Right Mouse

## Screen / Region Context Menu

Name	Function	Surface menu location	Hotkey
Context Menu	Calls the Right Mouse menu	Every menu bar	Right Mouse

## View 2D

### View 2D

Name	Function	Surface menu location	Hotkey
Scroller Activate	Zooms in and out in Compositing and Texture Node editor	None	Left Mouse
Scroller Activate	Zooms in and out in Compositing and Texture Node editor	None	Middle Mouse
Pan View	Pans the view in Compositing and Texture Node editor	None	Middle Mouse
Pan View	Pans the view in Compositing and Texture Node editor	None	Shift Middle Mouse
Pan View	Pans the view in Compositing and Texture Node editor	None	Mouse/ Trackpad pan
Scroll right	Zooms in and out in Compositing and Texture Node editor	None	Ctrl Wheel down
Scroll left	Zooms in and out in Compositing and Texture Node editor	None	Ctrl Wheel up
Scroll down	Zooms in and out in Compositing and Texture Node editor	None	Shift Wheel down
Scroll up	Zooms in and out in Compositing and Texture Node editor	None	Shift Wheel up
NDOF Pan/Zoom	Ndof device for 3dConnexion	None	Ndof Motion
Zoom out	Zooms in and out in Compositing and Texture Node editor	UV Editor / View / View Zoom Out	Wheel out
Zoom in	Zooms in and out in Compositing and Texture Node editor	UV Editor / View / View Zoom In	Wheel in
Zoom out	Zooms in and out in Compositing and Texture Node editor	None	Numpad -
Zoom in	Zooms in and out in Compositing and Texture Node editor	None	Numpad +
Zoom 2D View	Zooms in and out in Compositing and Texture Node editor	None	Ctrl Mouse/ Trackpad pan
Smooth view 2D	???	None	Timer 1
Scroll down	Zooms in and out in Compositing and Texture Node editor	None	Wheel down
Scroll up	Zooms in and out in Compositing and Texture Node editor	None	Wheel up
Scroll right	Zooms in and out in Compositing and Texture Node editor	None	Wheel down
Scroll left	Zooms in and out in Compositing and Texture Node editor	None	Wheel up
Zoom 2D View	Zooms in and out in Compositing and Texture Node editor	None	Ctrl Middle Mouse

View 2D			
Zoom 2D View	Zooms in and out in Compositing and Texture Node editor	None	Mouse/Trackpad Zoom
Zoom Border	Calls the Zoom border navigation in Compositing and Texture Node editor	None	Shift B

## View 2D Buttons List

View 2D Buttons List			
Name	Function	Surface menu location	Hotkey
Scroller Activate	UV Editor Tool shelf navigation	None	Left Mouse
Scroller Activate	UV Editor Tool shelf navigation	None	Middle Mouse
Pan View	UV Editor Tool shelf navigation	None	Middle Mouse
Scroller Activate	UV Editor Tool shelf navigation	None	Mouse /Trackpad Pan
Scroll down	UV Editor Tool shelf navigation	None	Wheel down
Scroll up	UV Editor Tool shelf navigation	None	Wheel up
Scroll down	UV Editor Tool shelf navigation	None	Page down
Scroll up	UV Editor Tool shelf navigation	None	Page Up
Zoom 2D View	UV Editor Tool shelf navigation	None	Ctrl Middle Mouse
Zoom 2D View	UV Editor Tool shelf navigation	None	Mouse/ Trackpad Zoom
Zoom 2D View	UV Editor Tool shelf navigation	None	Ctrl Mouse/Trackpad Pan
Zoom out	UV Editor Tool shelf navigation	None	Numpad -
Zoom in	UV Editor Tool shelf navigation	None	Numpad +
Reset View	UV Editor Tool shelf navigation	None	Home

## User Interface

User Interface			
Name	Function	Surface menu location	Hotkey
Eyedropper	Pick color	None	E
Eyedropper Colorband	Pick color	None	E
Eyedropper Colorband (points)	Pick color	None	Alt+E
Eyedropper Datablock	Pick color	None	E
Eyedropper Depth	Pick color	None	E
Copy Data Path	Copy Data Path	None	Shift Ctrl C
Copy Data Path	Copy Data Path	None	Shift Ctrl Alt C
Insert Keyframe ( Buttons )	Insert Keyframes at buttons	None	I
Delete Keyframe ( Buttons )	Delete Keyframes at buttons	None	Alt I
Clear Keyframe ( Buttons )	Clears Keyframes at buttons	None	Shift Alt I
Add Driver	Add Driver	None	Ctrl D
Remove Driver	Remove Driver	None	Ctrl Alt D
Add to Keying Set	Add to Keying Set	None	K

User Interface			
Remove from Keying Set	Remove from Keying Set	None	Alt K
Reset to Default Value	Resets the prop under the mouse to its default value	None	Backspace
Rename View Item	Renames the view item in the Category Shelf	Asset Browser Category Shelf	F2

## 3D View

3D View / 3D View (Global)			
Name	Function	Surface menu location	Hotkey
Reset 3D View	Resets the 3D View		Numpad *
Set 3D Cursor	Sets the 3D cursor position to Mouse position.	None	Alt Right Mouse
Local View	Switches to local view and back, just showing the selection then	3D View / View menu	Numpad /
Remove from Local View	Removes the selected object from the local view	3D View / View menu	Ctrl Numpad /
Rotate View	Rotate view	None	Right Mouse
Pan View	Move view	3D view / tool shelf /tools tab / transform panel / Translate Button	Shift Middle Mouse
Zoom View	Zoom view. See also the other zoom methods.	3D view / tool shelf /tools tab / transform panel / Scale Button	Ctrl Middle Mouse
Dolly View	Dolly View moves the World camera forward or backward. <b>Be careful with that one! You can trap yourself that regular zoom seems to have no more effect.</b>	3D Viewport / View / Navigation / Dolly Zoom	Shift Ctrl Middle Mouse
View Selected	Brings the selected object into focus. <b>With all regions.</b>	3D Viewport / View / View Selected all Regions	Ctrl Numpad 0
View Selected	Brings the selected object into focus	3D Viewport / View / View Selected	Numpad 0
Smooth View	???	None	Timer 1
Rotate View	Rotates the view with trackpad	None	Mouse/Trackpad pan
Rotate View	Rotates the view with trackpad	None	Mouse/Trackpad Rotate
Move View	Moves the view with trackpad	None	Shift Mouse/Trackpad pan
Zoom View	Zooms the view with trackpad	None	Mouse/Trackpad Zoom
Zoom View	Zooms the view with trackpad	None	Ctrl Mouse/Trackpad pan
Zoom View	Zooms in	3D Viewport / View / View Selected	Numpad +
Zoom View	Zooms out	3D Viewport / View / View Selected	Numpad -
Zoom View	Zooms in	None	Ctrl = ( german keyboard Ctrl *)
Zoom View	Zooms out	None	Ctrl -
Zoom View	Zooms in	None	Wheel in
Zoom View	Zooms out	None	Wheel out

<b>3D View / 3D View (Global)</b>			
Dolly View	Moves in. Dolly View moves the World camera forward or backward. <b>Be careful with that one! You can trap yourself that regular zoom seems to have no more effect.</b>	None	Shift Numpad +
Dolly View	Moves out. Dolly View moves the World camera forward or backward. <b>Be careful with that one! You can trap yourself that regular zoom seems to have no more effect.</b>	None	Shift Numpad -
Dolly View	Moves in. Dolly View moves the World camera forward or backward. <b>Be careful with that one! You can trap yourself that regular zoom seems to have no more effect.</b>	None	Shift Ctrl = ( german keyboard Shift Ctrl *)
Dolly View	Moves out. Dolly View moves the World camera forward or backward. <b>Be careful with that one! You can trap yourself that regular zoom seems to have no more effect.</b>	None	Shift Ctrl -
Frame Camera bounds	Fits the camera passepartout into the viewport	3D Viewport / View / View Camera Center	Home (Pos1 at german keyboard)
View Lock Center	Center the view lock offset	3D Viewport / View / Align View	Home (Pos1 at german keyboard)
Frame All	View all objects in the scene	3D Viewport / View / View all	Home (Pos1 at german keyboard)
Frame All	View all objects in the scene in all regions.	None	Ctrl Home
Frame All	View and center all objects in the scene	None	Shift C
View	Calls the pivot point pie menu	None	` (german keyboard . )
View Navigation	Enters the Walk/Fly mode	Navi / View navigation (Walk/Fly)	Shift ` (german keyboard Shift . )
View Camera	Enters or leaves the camera view.	3D Viewport / View / Active Camera	Numpad ,
View Numpad	Switches to Front Ortho sight	3D Viewport / View / Front	Numpad 1
View Orbit	Orbit down	3D Viewport / View / Navigation / Orbit down	Numpad 2
View Numpad	Switches to Left Ortho sight	3D Viewport / View / Front	Numpad 3
View Orbit	Orbit Left	3D Viewport / View / Navigation / Orbit Left	Numpad 4
View Persp/ Ortho	Changes between orthographic and perspective presentation of the 3D viewport.	3D Viewport / View / View Persp/Ortho	Numpad 5
View Orbit	Orbit Right	3D Viewport / View / Navigation / Orbit Right	Numpad 6
View Numpad	Switches to Top Ortho sight	3D Viewport / View / Top	Numpad 7
View Orbit	Orbit Up	3D Viewport / View / Navigation / Orbit Up	Numpad 8
View Numpad	Switches to Back Ortho sight	3D Viewport / View / Back	Ctrl Numpad 1
View Numpad	Switches to Left Ortho sight	3D Viewport / View / Left	Ctrl Numpad 3
View Numpad	Switches to Bottom Ortho sight	3D Viewport / View / Bottom	Ctrl Numpad 7
View Pan	Moves the view down	3D Viewport / View / Pan down	Ctrl Numpad 2

<b>3D View / 3D View (Global)</b>			
View Pan	Moves the view left	3D Viewport / View / Pan Left	Ctrl Numpad 4
View Pan	Moves the view right	3D Viewport / View / Pan Right	Ctrl Numpad 6
View Pan	Moves the view up	3D Viewport / View / Pan Up	Ctrl Numpad 8
View Orbit	Mirrors the axis orientation	3D Viewport / View / Navigation / Orbit opposite	Numpad 9
View Axis	Switches to Front Ortho, but with the selected Object in center.	3D Viewport / View / Align View / Front	Shift Numpad 1
View Axis	Switches to Right Ortho, but with the selected Object in center.	3D Viewport / View / Align View / Right	Shift Numpad 3
View Axis	Switches to Top Ortho, but with the selected Object in center.	3D Viewport / View / Align View / Top	Shift Numpad 7
View Axis	Switches to Back Ortho, but with the selected Object in center.	3D Viewport / View / Align View / Back	Shift Ctrl Numpad 1
View Axis	Switches to Left Ortho, but with the selected Object in center.	3D Viewport / View / Align View / Left	Shift Ctrl Numpad 3
View Axis	Switches to Bottom Ortho, but with the selected Object in center.	3D Viewport / View / Align View / Bottom	Shift Ctrl Numpad 7

Select	Activate/Select	None	Shift Ctrl Left Mouse
Select	Activate/Select	None	Ctrl Alt Left Mouse
Select	Activate/Select	None	Shift Alt Left Mouse
Select	Activate/Select	None	Shift Ctrl Alt Left Mouse

<b>3D View / 3D View (Global)</b>			
Lasso Select	Lasso Select, select	3D Viewport / Select / Lasso Select	Tweak Right Any
Lasso Select	Lasso Select, deselect	None	Tweak Right Any
Zoom Border	Zoom in our out by drawing a border	3D Viewport / Navi	Shift B
Copy Objects	Copy	3D Viewport / Object / Copy	Ctrl C
Paste Objects	Paste	3D Viewport / Object / Paste	Ctrl V
Snap	Calls the Snap Pie Menu	None	Shift E
Move	Move	None	Tweak Left Any
Interactive Light Track to Cursor	Navigate a lamp of type sun or spot light to point at objects	None	Shift T
Pivot Point	Call pivot pie menu	None	.
Orientation	Call orientation pie menu	None	,
Set Tool by Name	Cycles through the select methods	The select tools are in the toolbar	Shift Q
Pan View	Pans the view	None	Middle Mouse
Rotate View	Rotates the view	None	Alt Middle Mouse
Toggle X Ray	Toggles the x ray mode in edit mode	Header	Alt Z
Toggle X Ray	Toggles the x ray mode in edit mode	Header	Alt Y
Move	Legacy move tool	Navi menu	Ctrl W
Rotate	Legacy rotate tool	Navi menu	Ctrl E
Scale	Legacy scale tool	Navi menu	Ctrl R
Context Toggle - Widgets	Toggles the gizmos in the 3d view	Header	Shift + Tab
Context Toggle - Overlays	Toggles the overlays in the 3D	Header	Tab

## 3D View - Object Mode

<b>3D View - Object Mode - Object Mode (Global)</b>			
Name	Function	Surface menu location	Hotkey
Groundplane	Creates a groundplane	Isocam Add-on - Add menu	Shift Ctrl Alt 4
Gameisocam4to3	Creates a camera	Isocam Add-on - Add menu	Shift Ctrl Alt 3
Gameisocam	Creates a camera	Isocam Add-on - Add menu	Shift Ctrl Alt 2
Trueisocam	Creates a camera	Isocam Add-on - Add menu	Shift Ctrl Alt 1
(De)select All	Select all / Deselect all	3D Viewport / Select /	A
Select None	Deselects all	3D Viewport / Select /	Alt A
Select Inverse	Inverse selection	3D Viewport / Select /	Ctrl I
(De)select All	Deselects all	None	dbl - A
Make Parent	Make Parent	3D Viewport / Object / Parent	Ctrl P
Clear Parent	Clears the Parent relationship	3D Viewport / Object / Parent	Alt P
Delete	Delete	3D Viewport / Object / Delete	Delete
Duplicate Objects	Duplicate Objects	3D Viewport / Object / Duplicate Objects	Shift D
Duplicate Linked	Duplicate linked Objects	3D Viewport / Object / Duplicate Linked	Alt D

<b>3D View - Object Mode - Object Mode (Global)</b>			
Join	Join Object	3D Viewport / Object / Join	Ctrl J
Subdivision Set	Adds a SDS modifier to selected object and sets SDS Level to value	3D Viewport / Object / Subdivide / Subdivision Set	Ctrl 0
Subdivision Set	Adds a SDS modifier to selected object and sets SDS Level to value	3D Viewport / Object / Subdivide / Subdivision Set	Ctrl 1
Subdivision Set	Adds a SDS modifier to selected object and sets SDS Level to value	3D Viewport / Object / Subdivide / Subdivision Set	Ctrl 2
Subdivision Set	Adds a SDS modifier to selected object and sets SDS Level to value	3D Viewport / Object / Subdivide / Subdivision Set	Ctrl 3
Subdivision Set	Adds a SDS modifier to selected object and sets SDS Level to value	3D Viewport / Object / Subdivide / Subdivision Set	Ctrl 4
Subdivision Set	Adds a SDS modifier to selected object and sets SDS Level to value	3D Viewport / Object / Subdivide / Subdivision Set	Ctrl 5
Show hidden Objects	Show hidden objects	3D View / Object / Show Hide	Alt H
Hide Objects	Hide selected Objects	3D View / Object / Show Hide	H
Insert Keyframe	Inserts Default or Set Keying Set keyframes	3D View / Object / Animation	I
Insert Keying Set Menu	Calls the Keying Set menu	3D View / Object / Animation	K
Delete Keyframe	Delete Keyframe	3D View / Object / Animation	Alt I
Hide Unselected	Hide unselected objects	3D View / Object / Show Hide	Shift H
Object Context Menu	Calls a menu under the mouse	None	Right Mouse Click
Set Tool by Name	builtin.select_box	Tool shelf	B
Set Tool by Name	builtin.select_circle	Tool shelf	G
Set Tool by Name	builtin.move	Tool shelf	W
Set Tool by Name	builtin.rotate	Tool shelf	E
Set Tool by Name	builtin.scale	Tool shelf	R
Set Tool by Name	builtin.select	Tool shelf	D
Select Collection Group	Selects all in a Collection Group	3D Viewport	dbl - Shift Left Mouse
Select Collection Group (Extended)	Selects all in a Collection Group and extends current selection	3D Viewport	dbl - Ctrl Shift Left Mouse
Add Menu	Calls a floating Add Menu	3D Viewport	Shift A

<b>3D View - Object Mode - 3D View Tool : Tweak</b>			
Name	Function	Surface menu location	Hotkey
Select	Select all / Deselect all	Tool shelf	Left Mouse
Select	Toggle selection	Tool shelf	Shift Left Mouse

<b>3D View - Object Mode - 3D View Tool : Select Box</b>			
Name	Function	Surface menu location	Hotkey
Box Select	Select	Tool shelf	Tweak Left Any
Box Select	Add to selection	Tool shelf	Shift Tweak Left Any
Box Select	Subtract from selection	Tool shelf	Ctrl Tweak Left Any
Box Select	Intersect selection	Tool shelf	Shift Ctrl Tweak Left Any

**3D View - Object Mode - 3D View Tool : Select Circle**

Name	Function	Surface menu location	Hotkey
Circle Select	Select	Tool shelf	Left Mouse

## 42 - Important Hotkeys

The usage of Bforartists is UI centered. You should get away with using the tools from the UI, and not by hotkeys. And we have reduced the keymap dramatically compared to the Blender keymap.

There are however a few important hotkeys left that makes your life easier. And there are still some hotkeys that you simply need. Like the navigation with the mouse, which is also some kind of a hotkey.

Here we list some of the most used and basic hotkeys at one sheet, so that you don't have to dig through the manual and the whole keymap chapter or the menus to find the basic functionality.

### 3D view

All Modes			
<b>Move view</b>	MMB	<b>Move selection</b>	W
<b>Rotate view</b>	RMB / Alt + MMB	<b>Rotate selection</b>	E
<b>Zoom view</b>	Scrollwheel / Ctrl + MMB	<b>Scale selection</b>	R
<b>Trackball rotation</b>	2 x E	<b>Render Image</b>	F12
<b>Switch to Cameraview</b>	Numpad 0		

Switch views to orthographic			
<b>Ortho front</b>	Numpad 1	<b>Ortho right</b>	Numpad 3
<b>Ortho back</b>	Ctrl + Numpad 1	<b>Ortho top</b>	Numpad 7
<b>Ortho left</b>	Ctrl + Numpad 3	<b>Ortho bottom</b>	Ctrl + Numpad 7
To leave the orthographic views rotate the view.			

Select			
<b>Tweak</b>	D	<b>Lasso Select</b>	RMB
<b>Box Select</b>	B	<b>Add to / Remove from selection</b>	Hold Shift
<b>Select Circle</b>	G		

Modes			
<b>Object Mode</b>	1	<b>Vertex Paint</b>	4
<b>Edit Mode</b>	2	<b>Weight Paint</b>	5

<b>Sculpt Mode</b>	3	<b>Texture paint</b>	6
<b>Pose Mode</b>	0
